

**UNITED STATES DEPARTMENT OF THE INTERIOR  
NATIONAL PARK SERVICE  
FINAL CAPE HATTERAS NATIONAL SEASHORE OFF-ROAD VEHICLE MANAGEMENT PLAN /  
ENVIRONMENTAL IMPACT STATEMENT**

Cape Hatteras National Seashore, North Carolina

Lead Agency: National Park Service (NPS), U.S. Department of the Interior

This final *Cape Hatteras National Seashore Off-Road Vehicle Management Plan / Environmental Impact Statement* (plan/EIS) evaluates the impacts of a range of alternatives for regulations and procedures that would carefully manage off-road vehicle (ORV) use/access in the Cape Hatteras National Seashore (Seashore) to protect and preserve natural and cultural resources and natural processes, to provide a variety of visitor use experiences while minimizing conflicts among various users, and to promote the safety of all visitors. Executive Order 11644 of 1972, amended by Executive Order 11989 of 1977, requires certain federal agencies permitting ORV use on agency lands to publish regulations designating specific trails and areas for this use. Title 36, section 4.10 of the Code of Federal Regulations implements the executive orders by providing that routes and areas designated for ORV use shall be promulgated as special regulations. Upon conclusion of this plan and decision-making process, the alternative selected for implementation will become the ORV management plan and will form the basis for a special regulation, guiding the management and control of ORVs at the Seashore for the next 10 to 15 years.

This plan/EIS evaluates the impacts of two no-action alternatives (A and B) and four action alternatives (C, D, E and F). Alternative A would manage ORV use and access at the Seashore based on the 2007 Finding of No Significant Impact (FONSI) for the *Cape Hatteras National Seashore Interim Protected Species Management Strategy / Environmental Assessment* and the Superintendent's Compendium 2007, as well as elements from the 1978 draft interim ORV management plan that were incorporated in Superintendent's Order 7. Alternative B would manage ORV use in the same manner as alternative A, except as modified by the consent decree, as amended, which has been in effect at the Seashore since 2008. Alternative C would provide visitors to the Seashore with a degree of predictability regarding areas available for ORV use, as well as vehicle-free areas, based largely on the seasonal resource and visitor use characteristics of various areas in the Seashore. Under alternative D, visitors to the Seashore would have the maximum amount of predictability regarding areas available for ORV use and vehicle-free areas for pedestrian use with most areas having year-round, rather than seasonal, designations. Restrictions would be applied to larger areas over longer periods of time to minimize changes in designated ORV and vehicle-free areas over the course of the year. **Alternative D is the environmentally preferable alternative.** Alternative E would provide for additional flexibility in access for both ORV and pedestrian users, including allowing some level of overnight vehicle use at selected points and spits. Where greater access is permitted, often additional controls or restrictions would be in place to limit impacts on sensitive resources. Alternative F provides a similar mileage of year-round ORV routes as the other action alternatives but provides more ORV and pedestrian access than alternative D by improving interdunal road access and enhancing pedestrian facilities and opportunities. **Alternative F is the NPS Preferred Alternative.** The plan/EIS analyzes impacts of these alternatives in detail for floodplains, wetlands, federally listed threatened or endangered species, state-listed and special status species, wildlife and wildlife habitat, visitor use and experience, soundscapes, socioeconomics, and Seashore operations.

The NPS notice of availability for the draft plan/EIS was published in the *Federal Register* on March 5, 2010. The draft plan/EIS was posted online at the NPS PEPC website at <http://parkplanning.nps.gov/caha> on March 5, 2010. The U.S. Environmental Protection Agency (EPA) notice of availability for the draft plan/EIS was published on March 12, 2010, which opened the public comment period and established the closing date of May 11, 2010, for comments. Responses to public and agency comments received on the draft plan/EIS are included as appendix C and, where needed, as text changes in this final plan/EIS. A copy of the original draft plan/EIS showing all additions, deletions, and other changes that have been made in the preparation of this final plan/EIS, including minor editorial changes, is available electronically at <http://parkplanning.nps.gov/caha>.

The publication of the EPA notice of availability of this final plan/EIS in the *Federal Register* will initiate a 30-day wait-period before the Regional Director of the Southeast Region will sign the Record of Decision, documenting the selection of an alternative to be implemented. After the NPS publishes a notice in the *Federal Register* announcing the availability of the signed Record of Decision, implementation of the alternative selected in the Record of Decision can begin.

**CAPE HATTERAS NATIONAL SEASHORE  
OFF-ROAD VEHICLE MANAGEMENT PLAN  
FINAL ENVIRONMENTAL IMPACT STATEMENT**

November 2010

0037688

## EXECUTIVE SUMMARY

This final *Cape Hatteras National Seashore Off-Road Vehicle Management Plan / Environmental Impact Statement* (plan/EIS) analyzes a range of alternatives and actions for the management of off-road vehicles (ORVs) at Cape Hatteras National Seashore (the Seashore). The plan/EIS assesses the impacts that could result from continuation of current management actions in existence during the planning period for this plan/EIS (the two “no-action” alternatives) or implementation of any of the four action alternatives.

Upon conclusion of the planning and decision-making process, the alternative selected for implementation will become the ORV management plan, which will guide the management and control of ORVs at the Seashore for the next 10 to 15 years. It will also form the basis for a special regulation to manage ORV use at the Seashore.

### BACKGROUND

Officially authorized in 1937 along the Outer Banks of North Carolina, Cape Hatteras is the nation’s first national seashore. Consisting of more than 30,000 acres distributed along approximately 67<sup>1</sup> miles of shoreline, the Seashore is part of a dynamic barrier island system.

The Seashore serves as a popular recreation destination with more than 2.1 million visitors in 2008 (NPS 2008e), showing an 8-fold increase in visitation since 1955 (NPS 2007f). Seashore visitors participate in a variety of recreational activities, including beach recreation (sunbathing, swimming, shell collecting, etc.), fishing (surf and boat), hiking, hunting, motorized boating, nonmotorized boating (sailing, kayaking, canoeing), nature study, photography, ORV use (beach driving), shellfishing, sightseeing, watersports (surfing, windsurfing, kiteboarding, etc.), and wildlife viewing. Seashore visitors use ORVs for traveling to and from swimming, fishing, and surfing areas and for pleasure driving.

Current management practices at the Seashore allow ORV users to drive on the beach seaward of the primary dune line, with a 10-meter backshore area seaward of the primary dune line protected seasonally. Drivers must use designated ramps to cross between the beach and NC-12 that runs behind the primary dune line. In addition to a multitude of visitor opportunities, the Seashore provides a variety of important habitats created by its dynamic environmental processes, including habitats for the federally listed piping plover; sea turtles; and one listed plant species, the seabeach amaranth. The Seashore contains ecologically important habitats such as marshes, tidal flats, and riparian areas, and hosts various species of concern such as colonial waterbirds (least terns, common terns, and black skimmers), American oystercatcher, and Wilson’s plover, all of which are listed by the North Carolina Wildlife Resources Commission (NCWRC) as species of special concern. In addition, the gull-billed tern, also found at the Seashore, is listed by the NCWRC as threatened.

Historically, beach driving at the Seashore was for the purpose of transportation, and not recreation. The paving of NC-12, the completion of the Bonner Bridge connecting Bodie and Hatteras islands in 1963, and the introduction of the State of North Carolina ferry system to Ocracoke Island facilitated visitor access to the sound and ocean beaches. Improved access, increased population, and the popularity of the sport utility vehicle have resulted in a dramatic increase in vehicle use on Seashore beaches.

---

<sup>1</sup> Due to the dynamic nature of the barrier island system, the mileage of shoreline in the Seashore is constantly changing. This mileage estimate includes ocean shoreline and some interdunal roads managed for public recreation by the NPS. Actual on-the-ground mileage may vary, especially around the inlets and spits, due to the increased potential for erosion and accretion in these areas.

ORV use at the Seashore has historically been managed since the 1970s through various draft or proposed plans, though none were ever finalized or published as a special regulation as required by Executive Orders 11644 and 11989 and 36 Code of Federal Regulations (CFR) 4.10. Motivated in part by a decline in most beach nesting bird populations on the Seashore since the 1990s, in July 2007 the NPS finalized the *Cape Hatteras National Seashore Interim Protected Species Management Strategy / Environmental Assessment* (Interim Strategy) to provide resource protection guidance until the long-term ORV management plan and regulation could be completed. In October 2007, a lawsuit was filed on the Interim Strategy that resulted in a consent decree in April 2008. As a part of the consent decree, the court ordered deadlines for completion of an ORV management plan/EIS and special regulation. This document, once finalized and approved, will serve as the ORV management plan and will form the basis for the special regulation governing ORV use at the Seashore.

## **PURPOSE OF THE PLAN**

The purpose of this plan is to develop regulations and procedures that carefully manage ORV use/access in the Seashore to protect and preserve natural and cultural resources and natural processes, to provide a variety of visitor use experiences while minimizing conflicts among various users, and to promote the safety of all visitors.

## **NEED FOR ACTION**

Cape Hatteras National Seashore provides a variety of visitor experiences. It is a long, essentially linear park, visitation is high, and parking spaces near roads are limited. Some popular beach sites, particularly those near the inlets and Cape Point, are a distance from established or possible parking spaces. Visitors who come for some popular recreational activities such as surf fishing and picnicking are accustomed to using large amounts and types of recreational equipment that cannot practically be hauled over these distances by most visitors without some form of motorized access. For many visitors, the time needed and the physical challenge of hiking to the distant sites, or for some even to close sites, can discourage or preclude access by nonmotorized means. As a result, ORVs have long served as a primary form of access for many portions of the beach in the Seashore, and continue to be the most practical available means of access and parking for many visitors.

In addition to these recreation opportunities, the Seashore is home to important habitats created by the Seashore's dynamic environmental processes, including habitats for several federally listed species including the piping plover and three species of sea turtles. These habitats are also home to numerous other protected species, as well as other wildlife. The NPS is required to conserve and protect all of these species, as well as the other resources and values of the Seashore. In addition, the Seashore was designated a Globally Important Bird Area by the American Bird Conservancy (American Bird Conservancy 2005). This designation recognizes those areas with populations and habitat important at the global level.

The use of ORVs must therefore be regulated in a manner that is consistent with applicable law, and appropriately addresses resource protection (including protected, threatened, or endangered species), potential conflicts among the various Seashore users, and visitor safety. Section 4.10(b) of the regulations in Title 36 of the Code of Federal Regulations, which implements Executive Orders 11644 and 11989, prohibits off-road use of motor vehicles except on designated routes or areas. It requires that "routes and areas designated for ORV use shall be promulgated as special regulations" in compliance with other applicable laws.

Therefore, in order to provide continued visitor access through the use of ORVs, the NPS must promulgate a special regulation authorizing ORV use at the Seashore. In order to ensure that ORV use is

consistent with applicable laws and policies, the Seashore has determined that an ORV management plan is necessary as part of this process. Thus, the ORV plan and special regulation will

- Bring the Seashore in compliance with Executive Orders 11644 and 11989 respecting ORV use, and with NPS laws, regulations (36 CFR 4.10), and policies to minimize impacts to Seashore resources and values.
- Address the lack of an approved plan, which has led over time to inconsistent management of ORV use, user conflicts, and safety concerns.
- Provide for protected species management in relation to ORV use by replacing the Interim Strategy (NPS 2006a), and associated Biological Opinion and amendments (USFWS 2006a, 2007a, 2008a) as modified by the consent decree.

## **OBJECTIVES IN TAKING ACTION**

### **MANAGEMENT METHODOLOGY**

- Identify criteria to designate ORV use areas and routes.
- Establish ORV management practices and procedures that have the ability to adapt in response to changes in the Seashore's dynamic physical and biological environment.
- Establish a civic engagement component for ORV management.
- Establish procedures for prompt and efficient public notification of beach access status including any temporary ORV use restrictions for such things as ramp maintenance, resource and public safety closures, storm events, etc.
- Build stewardship through public awareness and understanding of NPS resource management and visitor use policies and responsibilities as they pertain to the Seashore and ORV management.

### **NATURAL PHYSICAL RESOURCES**

- Minimize impacts from ORV use to soils and topographic features, for example, dunes, ocean beach, wetlands, tidal flats, and other features.

### **THREATENED, ENDANGERED, AND OTHER PROTECTED SPECIES**

- Provide protection for threatened, endangered, and other protected species (e.g., state-listed species) and their habitats, and minimize impacts related to ORV and other uses as required by laws and policies, such as the *Endangered Species Act*, the *Migratory Bird Treaty Act*, and NPS laws and management policies.

### **VEGETATION**

- Minimize impacts to native plant species related to ORV use.

### **OTHER WILDLIFE AND WILDLIFE HABITAT**

- Minimize impacts to wildlife species and their habitats related to ORV use.

## **CULTURAL RESOURCES**

- Protect cultural resources, such as shipwrecks, archeological sites, and cultural landscapes, from impacts related to ORV use.

## **VISITOR USE AND EXPERIENCE**

- Ensure that ORV operators are informed about the rules and regulations regarding ORV use at the Seashore.
- Manage ORV use to allow for a variety of visitor use experiences.
- Minimize conflicts between ORV use and other uses.

## **VISITOR SAFETY**

- Ensure that ORV management promotes the safety of all visitors.

## **SEASHORE OPERATIONS**

- Identify operational needs and costs to fully implement an ORV management plan.
- Identify potential sources of funding necessary to implement an ORV management plan.
- Provide consistent guidelines, according to site conditions, for ORV routes, ramps, and signage.

## **PURPOSE AND SIGNIFICANCE OF CAPE HATTERAS NATIONAL SEASHORE**

### **PARK ENABLING LEGISLATION, PURPOSE, AND SIGNIFICANCE**

All units of the national park system were formed for a specific purpose (the reason they are significant) and to conserve significant resources or values for the enjoyment of future generations. The purpose and significance of the park provides the basis for identifying uses and values that individual NPS plans will support. The following provides background on the purpose and significance of the Seashore.

As stated in the Seashore's enabling legislation (the Act), Congress authorized the Seashore in 1937 as a national seashore for the enjoyment and benefit of the people, and to preserve the area. The Act states:

Except for certain portions of the area, deemed to be especially adaptable for recreational uses, particularly swimming, boating, sailing, fishing, and other recreational activities of similar nature, which shall be developed for such uses as needed, the said areas shall be permanently reserved as a primitive wilderness and no development of the project or plan for the convenience of visitors shall be undertaken which would be incompatible with the preservation of the unique flora and fauna or the physiographic conditions now prevailing in this area.

The Act also states:

...when title to all the lands, except those within the limits of established villages, within boundaries to be designated by the Secretary of Interior within the area of approximately one hundred square miles on the islands of Chicamacomico [Hatteras], Ocracoke, Bodie, Roanoke, and Collington, and the waters and the lands beneath the waters adjacent there

to shall have been vested in the United States, said areas shall be, and is hereby, established, dedicated, and set apart as a national seashore for the benefit and enjoyment of the people and shall be known as the Cape Hatteras National Seashore.

A 1940 amendment to the enabling legislation authorized hunting and re-designated the area as the Cape Hatteras National Seashore Recreational Area. (Note: The history of the Seashore’s name is described in more detail in chapter 1.)

Park significance statements capture the essence of the park’s importance to the nation’s natural and cultural heritage. Understanding park significance helps managers make decisions that preserve the resources and values necessary to the park’s purpose. The following significance statements recognize the important features of the Seashore. As stated in the 2006–2011 Strategic Plan, the Seashore has the following significance (NPS 2007b):

This dynamic coastal barrier island system continually changes in response to natural forces of wind and wave. The flora and fauna that are found in a variety of habitats at the park include migratory birds and several threatened and endangered species. The islands are rich with maritime history of humankind’s attempt to survive at the edge of the sea, and with accounts of dangerous storms, shipwrecks, and valiant rescue efforts. Today, the Seashore provides unparalleled opportunities for millions to enjoy recreational pursuits in a unique natural seashore setting and to learn of the nation’s unique maritime heritage.

## ISSUES AND IMPACT TOPICS

Issues associated with implementing an ORV management plan at Cape Hatteras National Seashore were initially identified by Seashore staff during internal scoping and were further refined through the public scoping and negotiated rulemaking processes. Table ES-1 details the issues that were discussed and analyzed in the plan/EIS.

**TABLE ES-1. ISSUES AND IMPACT TOPICS**

Issue	Reason for Analysis
Wetlands and Floodplains	<p>Vegetated wetlands along the soundside and interior of the islands are susceptible to direct damage from ORV use.</p> <p>Estuarine wetlands can be denuded of vegetation when ORVs are driven and parked along the soundside shoreline.</p> <p>Many of the interior or interdunal roads are located near wetland areas that are often not noticeable to visitors. When standing water is present along these ORV routes, visitors may drive over adjacent vegetated areas in an attempt to avoid the standing water. This results in wider roads, new vehicle routes, and crushed or dead vegetation.</p> <p>Construction of new parking areas is of concern for wetlands that may be located nearby.</p> <p>Nearly all of the Seashore is located within the 100-year floodplain, with the exception of a small area at the Navy tower site on Bodie Island and larger areas around Buxton, and could be impacted by the proposed development of ramps and parking areas under this plan/EIS.</p>

Issue	Reason for Analysis
Federally Listed Threatened or Endangered Species	<p>The Seashore is home to federally threatened and endangered species year-round. Increased year-round visitation results in a greater potential for conflicts between visitor use and listed species. Conflicts between listed species and recreational use (including ORV use) could create direct or indirect losses to a listed species.</p> <p>The Seashore is used by both the threatened Atlantic Coast population of piping plover for breeding and wintering and by the endangered Great Lakes population (considered threatened on its wintering grounds) for wintering. Seabeach amaranth, a federally listed threatened plant species, has been found in limited numbers at the Seashore in the recent past. Three species of federally listed sea turtles (loggerhead, green, and leatherback) nest on Seashore beaches, with loggerhead being the most common.</p>
State-Listed and Special Status Species	<p>Habitat for state-listed and special status species, such as the American oystercatcher and several species of colonial waterbirds, may be vulnerable to disturbances caused by recreational uses, including ORV use.</p> <p>The gull-billed tern is a state-listed threatened species in North Carolina. American oystercatcher, Wilson's plover, least tern, common tern, and black skimmer are listed by the NCWRC as species of special concern.</p> <p>In addition, the American oystercatcher is listed as a species of concern by the Southeastern Shorebird Conservation Plan, and both the American oystercatcher and the Wilson's plover are identified in the U.S. Shorebird Conservation Plan as "Species of High Concern." These species are also designated as Birds of Conservation Concern (USFWS 2008b) and/or Migratory Nongame Birds of Management Concern in the United States (USFWS 1995) which qualifies them as species of concern according to Executive Order 13186. All these state-listed or special status species have had historically low reproductive rates.</p>
Wildlife and Wildlife Habitat	<p>ORV use along the Seashore can disrupt habitat or cause a loss of habitat in high use areas. Habitat loss due to ORV use could also occur indirectly as a result of the noise and disturbance from this activity, specifically for other bird species (those not federally protected or of special concern) and invertebrates.</p>
Soundscapes	<p>Impacts related to soundscapes could occur wherever ORVs are allowed on the oceanside or the soundside. Vehicular noise has the potential to impact other recreational uses, such as bird watching or enjoying the solitude and natural soundscape of the Seashore. In addition to impacting soundscapes in relation to visitor enjoyment, vehicular noise could create unsuitable habitat for Seashore wildlife.</p>
Visitor Use and Experience	<p>ORV use at the Seashore is an integral component of the experience for some visitors and may be impacted by ORV management activities. Other Seashore visitors who are not using ORVs may be impacted by ORV use.</p> <p>Although some visitors want to use an ORV to access the Seashore, other visitors wish to engage in recreational activities on foot and away from the presence of motorized vehicles. Restricting ORVs from areas of the Seashore could enhance the recreational experience for some and diminish the experience for others. Visitor experience could be affected by conflicts between motorized and nonmotorized recreation users. A further component of visitor experience is providing for the safety of all visitors at the Seashore.</p> <p>Other issues related to visitor use and experience include viewsheds, aesthetics, and night skies. While the sight of ORVs can destroy the viewshed and aesthetics for some visitors, they also change the viewshed by altering the natural landscape.</p>
Socioeconomics	<p>Management or regulation of ORV use at the Seashore could impact the local economy by changing the demand for goods and services from ORV users in these communities. The eight villages located within the Seashore boundaries serve as access points to the Seashore for visitors, including ORV users. These villages receive economic benefit from the ORV users who take advantage of the goods and services these communities offer. The communities are concerned that if a permit system or other ORV restrictions are implemented that make it harder for ORV users to use the area, fewer tourists may come to the villages, resulting in impacts to the local economy.</p>

Issue	Reason for Analysis
Seashore Management and Operations	Accommodating recreational uses while protecting sensitive species requires a sufficient number of personnel and an adequate level of funding. Past anecdotal evidence suggested that the Seashore did not have enough personnel to properly enforce existing ORV management decisions. If operational requirements increase under the new ORV management plan, it would require an increased commitment of limited NPS resources (staff, money, time, and equipment).

## ALTERNATIVES

The *National Environmental Policy Act* (NEPA) requires federal agencies to explore a range of reasonable alternatives that address the purpose of and need for the action. The alternatives under consideration must include the “no-action” alternative as prescribed by 40 CFR 1502.14. Two no-action alternatives are included for analysis in this plan/EIS, because management changed part way through the planning process in May 2008, after the consent decree was signed (see chapter 1 for more information). Action alternatives may originate from the proponent agency, local government officials, or members of the public at public meetings or during the early stages of project development. Alternatives may also be developed in response to comments from coordinating or cooperating agencies.

The alternatives analyzed in this document, in accordance with NEPA, are the result of internal scoping, public scoping meetings, and information developed during the negotiated rulemaking process. These alternatives meet the management objectives of the Seashore, while also meeting the overall purpose of and need for the proposed action. Alternative elements that were considered but were not technically or economically feasible, did not meet the purpose of and need for the project, created unnecessary or excessive adverse impacts to resources, and/or conflicted with the overall management of the Seashore or its resources were dismissed from further analysis.

The elements of all six alternatives are detailed in tables ES-2, ES-2A, and ES-3. How each of these alternatives meets the objectives of the plan/EIS is detailed in table ES-4.

## ELEMENTS COMMON TO ALL ALTERNATIVES

The following describes elements of the alternatives that are common to all alternatives, including the no-action alternatives.

- **Vehicle/Operator Requirements.** Requirements for operators and their vehicles would be established that would require vehicles to meet all requirements to operate legally on state highways where the vehicle is registered, including any required vehicle equipment, as well as for drivers to have a valid vehicle registration, insurance, and license plate. Operators would also be required to observe any law applicable to vehicle use on a paved road in the State of North Carolina, hold a current driver’s license, and use a seatbelt.
- **Prohibited Activities.** Open containers of any type of alcoholic beverage are prohibited in vehicles and ORV drivers and/or passengers are prohibited from sitting on the tailgate or roof or hanging outside of moving vehicles.
- **Right-of-Way Requirements.** Right-of-way between vehicles is not defined by the Seashore, and the standard driving rules must be followed.
- **Ramp Configuration.** If Bonner Bridge construction closes ramp 4, a new ramp 3 would be constructed north of the Oregon Inlet campground and day-use parking would be provided.

- **Boat Access.** Launch sites, as designated under 36 CFR 3.8(a)(2), are identified in the Superintendent’s Compendium. Launching or recovery of vessels is prohibited within resource closures.
- **NPS Regulations.** Title 36: Parks, Forests, and Public Properties of the U.S. Code of Federal Regulations is applicable in all national parks, including Cape Hatteras National Seashore. These regulations include those in Title 36 applicable to the operation of ORVs in the Seashore and those applicable to individuals recreating at the Seashore. Of particular note are the provisions of 36 CFR 1.5 and 1.6, which state that the superintendent may impose public use limits, or close all or a portion of a park area to all public use or to a specific use or activity; designate areas for a specific use or activity; or impose conditions or restrictions on a use or activity, and may establish a permit, registration, or reservation system.
- **Enforcement.** Violations could result in fines or mandatory court appearances as defined in the *Collateral Schedule, Eastern District of North Carolina, National Park Service*.
- **Areas of Vehicle Operation.** Visitors accessing the Seashore by ORV must drive only on marked ORV routes, comply with posted restrictions, and adhere to the following:
  - Driving or parking outside of marked and maintained ORV routes is prohibited.
  - Operating a vehicle of any type within safety or resource closures is prohibited.
  - Accessing the beach and designated ORV routes is allowed only via designated beach access ramps and soundside access roads.
  - Reckless driving—for example, cutting circles or defacing the beach—is prohibited.
  - Observing pedestrian right-of-way is required.
  - During the shorebird and turtle breeding seasons, standard resource protection buffers would apply, which could restrict ORV access to certain areas of the Seashore. Refer to the “Visitor Use and Experience” section in chapter 3 for a description of access closures that occurred during the 2007-2010 seasons.
- **Commercial Fishing.** Commercial fishing permit holders with ORVs would be allowed to enter administrative and safety closures, but not resource closures or lifeguarded beaches. Two designated commercial fishing access points exist on the soundside of Ocracoke Island, where only vehicular access for commercial fishing is allowed.
- **Permitted Uses.** Kite flying, kite boards, and ball and Frisbee tossing are prohibited within or above all bird closures.
- **Commercial Use Authorization (CUA) permit holders** would not need to obtain an ORV permit in addition to the CUA permit. Customers of CUA permit holders who are operating an ORV while with the CUA holder would need to obtain the necessary permit for ORV use. **Protected Species Management.** In general, because of the dynamic nature of the Seashore beaches and inlets, protected species management could change by location and time; new sites (bars, islands) could require additional management, or management actions may become inapplicable for certain sites (e.g., habitat changes with vegetation growth, new overwash areas). The following would also occur:
  - Areas with symbolic fencing (string between posts) would be closed to recreational access.
  - Data collection would continue to document breeding and nest locations.
  - Essential vehicles could enter restricted areas subject to the guidelines in the Essential Vehicles section of the *U.S. Fish and Wildlife Service Piping Plover (Charadrius melodus)*,

*Atlantic Coast Population, Revised Recovery Plan* (USFWS 1996a). Due to the soft sand conditions of the Seashore, essential vehicles would be allowed to travel up to 10 miles per hour (mph).

- **Accessibility for Visitors with Disabilities.** The Seashore would provide access to visitors with disabilities as follows:
  - Beach access points and boardwalks would be provided at Coquina Beach, the Frisco Boathouse, the Ocracoke Pony Pen, and the Ocracoke day use area.
  - Beach access would be provided through the issuance of special use permits for areas in front of the villages to allow ORVs to transport visitors with disabilities to the beach and then return the vehicle back to the street.
  - Beach wheelchairs could be checked out at each District on a first-come, first-served basis.
- **Campgrounds.** The Seashore has four campgrounds at Oregon Inlet, Frisco, Cape Point, and Ocracoke. The campgrounds would be open seasonally. Dates the campgrounds open or close would be subject to change.
- **Fishing Facilities.** Fishing piers are located in Frisco<sup>2</sup>, Avon, and Rodanthe on Hatteras Island, and a marina is located at Oregon Inlet on Bodie Island. These would continue to be available to the public.
- **Education and Outreach.** The Seashore would continue to conduct education and outreach related to ORV management such as posting signage, putting out resource updates, and notifying the public of what areas of the beach are accessible.

## NO-ACTION ALTERNATIVES

The no-action alternative is developed for two reasons. First, a no-action alternative may represent the agency's past and current actions or inaction on an issue continued into the future, which may represent a viable alternative for meeting the agency's purpose and need. Second, a no-action alternative may serve to set a baseline of existing impacts continued into the future against which to compare the impacts of action alternatives. For most agency decisions, one no-action alternative can serve both of these purposes. Here, however, the situation is more complex.

As stated in chapter 1, "in order to provide continued visitor access through the use of ORVs, NPS must promulgate a special regulation authorizing ORV use at the Seashore," and the purpose of this plan, in part, is to develop such a regulation. Without a special regulation, continued ORV use would conflict with NPS regulations (36 CFR 4.10). The consent decree recognizes this and sets a deadline of April 1, 2011, for the promulgation of a final special regulation. As the district court has recognized in another case, absent an ORV plan and regulation, as a legal matter ORV use is prohibited. The NPS acknowledges that if it does not promulgate a special regulation to authorize ORV use, then ORV use would, in fact, be prohibited at the Seashore.

"No ORV use" thus could represent a result of NPS's past inaction continued into the future, and thus might satisfy the first purpose of a no-action alternative. It is not, however, a viable alternative for meeting the purpose and need for this action. It was considered but dismissed in the broader range of

---

<sup>2</sup> The Frisco pier was closed for public safety reasons due to deteriorating conditions, and then further damaged by Hurricane Earl in September 2010. The future of this pier is not known at this time.

alternatives that were identified. Included in chapter 1 is a discussion of the reasons that, for this plan/EIS, “Prohibit the Use of Off-Road Vehicles” is not considered a reasonable alternative.

NPS also does not believe that a “no ORV use” alternative would fully serve the function of a no-action alternative, because it would not satisfy the second purpose. It would not serve as an environmental baseline of existing impacts continued into the future against which to compare the impacts of action alternatives. ORV use has occurred continuously before and since the Seashore was authorized and established. Given this history, a complete ORV prohibition cannot be considered as the “current management direction or level of management intensity” or as “continuing with the present course of action,” which is how the Council on Environmental Quality describes this role of the “no-action” alternative under NEPA.

Because there is no history of prohibition at the Seashore, there are also no Seashore monitoring data for an analysis of its effects. Extrapolation from other sites that prohibit ORV use, and from experience with resource closures in limited locations and limited times at the Seashore, indicates that prohibition would likely benefit the Seashore’s wildlife more than the other alternatives, though benefits could be similar to those from alternative D. Prohibition would be easier for the Seashore to administer than the other alternatives, though it might increase the need for additional parking areas, with their attendant costs and effects. It would detract from the experience of those visitors who prefer ORVs for access, while enhancing the experience of other visitors who prefer beaches without the presence of vehicles. Prohibition would adversely affect the economies of the villages in the Seashore more than the other alternatives because ORV users would not have the opportunity to shift their visits to different areas of the Seashore or to different dates or times of day when driving would be allowed. These conclusions, however, are largely speculative and cannot substitute for a baseline of existing impacts.

Similarly, using the management measures enforced in 2004 (which were adopted from the 1978 draft plan) as a no-action alternative would fail to meet the agency’s purpose and need to regulate ORVs in a manner that is consistent with applicable law, and would not appropriately address resource protection (including protected, threatened, or endangered species), potential conflicts among the various Seashore users, and visitor safety. In addition, it would neither bring the Seashore into compliance with the criteria of Executive Orders 11644 and 11989 for designation of ORV routes nor meet the second purpose of a “no-action” alternative to serve as a baseline of existing impacts continued into the future against which to compare the impacts of action alternatives.

For this plan/EIS the range of alternatives includes two no-action alternatives. Alternative A represents continuing management as described in the Interim Strategy. This management strategy was challenged in court and subsequently modified by the consent decree that was signed on April 30, 2008. Alternative B represents continuing management as described in the consent decree. These two no-action alternatives are analyzed to capture the full range of management actions that occurred and are currently occurring during the planning process for this plan/EIS. Tables ES-2, ES-2A, and ES-3 compare the actions that would be taken under each alternative, and figure 2 in chapter 2 includes the maps of all alternatives.

## **NO-ACTION ALTERNATIVES**

**Alternative A – No Action: Continuation of Management under the Interim Protected Species Management Strategy.** Under this no-action alternative, management of ORV use and access at the Seashore would be a continuation of management based on the 2007 FONSI for the Interim Strategy and the Superintendent’s Compendium 2007, as well as elements from the 1978 draft interim ORV management plan that were incorporated in Superintendent’s Order 7. The Interim Strategy provides direction on the how, when, and where closures and buffers for federally listed species are established, and the size of buffers/closures. Buffer sizes for non-listed species allow some degree of flexibility and

management discretion. There would be no restriction on night driving or carrying capacity established under alternative A and an ORV permit would not be required. Seasonal ORV closures would be limited to the “village beaches” and the ocean and inlet shoreline and on the exiting soundside routes would be a potential ORV route.

**Alternative B – No Action: Continuation of Terms of the Consent Decree Signed April 30, 2008, and amended June 4, 2009.** Under alternative B, management of ORV use would follow the terms described under alternative A, except as modified by the provisions of the consent decree, as amended. Modifications in the consent decree include earlier and more frequent monitoring at key nesting areas and larger, non-discretionary resource protection buffers when breeding activity is observed. These modifications would result in earlier, larger, and longer-lasting ORV and pedestrian closures than alternative A. Alternative B would also prohibit night driving from 10:00 p.m. to 6:00 a.m. May 1 to September 15 and would allow night driving with a permit from September 16 to November 15. No carrying capacity would be established or ORV use permit required under alternative B, except for the night-driving permit from September 16 to November 15.

## **ACTION ALTERNATIVES**

Elements that are common to all action alternatives include the following:

- ORV routes and areas would be officially designated in accordance with the executive orders.
- Year-round ORV routes and areas would be designated only in locations without sensitive resources or high pedestrian use.
- Year-round vehicle-free areas would be designated.
- Management of protected shorebirds would be accomplished through the implementation of defined prenesting closures and breeding/nesting/unfledged chick buffers as detailed in chapter 2 (see tables 10 and 10-1). Management activities during the breeding season would focus on beach-nesting bird species such as the piping plover, Wilson’s plover, American oystercatcher, least tern, common tern, gull-billed tern, and black skimmer; however, there would be ongoing evaluation of the breeding shorebird species addressed by this plan as part of the periodic review process.
- Night-driving restrictions would be in effect from May 1 through November 15, which corresponds with turtle nesting season.
- ORV permits would be required and would involve a fee and education requirement.
- Overcrowding would be addressed using various methods for establishing carrying capacity.
- New vehicular access points and/or new or expanded parking areas would be identified.
- Commercial fishing vehicles would be exempted from some ORV restrictions, when not in conflict with resource protection.

**Alternative C – Seasonal Management.** Alternative C would provide visitors to the Seashore with a degree of predictability regarding areas available for ORV use, as well as vehicle-free areas, based largely on the seasonal resource and visitor use characteristics of various areas in the Seashore. Both seasonal and year-round ORV routes would be established, although most areas would have a seasonal focus. SMAs and some village beaches would be closed to ORV use from March 14 through October 14. Pedestrians would be able to access some SMAs depending upon specific shorebird breeding activity. Most of the seasonal ORV areas would be open to ORVs from October 15 through March 14. Seasonal night-driving

restrictions would be established between the hours of 7:00 p.m. and 7:00 a.m. from May 1 to November 15. An ORV carrying capacity would be established using a maximum number of vehicles per mile of beach area.

**Alternative D – Increased Predictability and Simplified Management. Alternative D is the Environmentally Preferable Alternative.** Under alternative D, visitors to the Seashore would have the maximum amount of predictability regarding areas available for ORV use and vehicle-free areas for pedestrian use. Restrictions would be applied to larger areas over longer periods of time to minimize changes in designated ORV and vehicle-free areas over the course of the year. To provide predictability under this alternative, only year-round ORV routes would be designated. Year-round vehicle-free areas would include all of the SMAs and village beaches. SMAs would be closed to pedestrian use under Management Level 1 (ML1) measures during the breeding season. Seasonal night-driving restrictions would be established between the hours of 7:00 p.m. and 7:00 a.m. from May 1 to November 15. An ORV carrying capacity would be addressed solely by the use of vehicle stacking limits (one vehicle deep).

**Alternative E – Variable Access and Maximum Management.** Alternative E would provide use areas for all types of visitors to the Seashore with a wide variety of access for both ORV and pedestrian users, but often with controls or restrictions in place to limit impacts on sensitive resources. Interdunal road and ramp access would be improved, and more pedestrian access would be provided through substantial additions to parking capacity at various key locations that lend themselves to walking on the beach. This alternative would close the SMAs to ORV use from March 15 through August 31, except that two spits and Cape Point would have initial ORV access corridors during the breeding season, with increased species monitoring in those areas. These ORV access corridors would close when breeding activity is observed. North Ocracoke Spit would be designated as a vehicle-free area year-round under alternative E, and village beaches would be closed to ORV use between April 1 and October 31. A seasonal night-driving restriction would be established from 10:00 p.m. to 6:00 a.m. during turtle nesting season although areas with low densities of turtle nests could open to night driving from September 16 through November 15. This alternative would offer a park-and-stay overnight option for ORVs at some spits and Cape Point during the turtle nesting season. Self-contained vehicle (SCV) camping would be allowed during the off-season at designated Seashore campgrounds under the terms of a permit. Alternative E would provide enhanced options for pedestrian access to Bodie Island Spit and South Point Ocracoke by promoting water taxi service when those areas are closed to ORVs.

**Alternative F – The NPS Preferred Alternative.** The NPS considered a variety of concepts and measures that either originated during the negotiated rulemaking process from members of the negotiated rulemaking advisory committee (Committee) or were discussed during Committee, subcommittee, or work group sessions. Although the Committee as a whole did not reach a consensus on a recommended alternative, in creating this action alternative the NPS made management judgments as to which combination of concepts and measures would make an effective overall ORV management strategy. This alternative is designed to provide visitors to the Seashore with a wide variety of access opportunities for both ORV and pedestrian users. Alternative F would provide a reasonably balanced approach to designating ORV routes and vehicle-free areas and providing for the protection of park resources. To support access to both vehicle-free areas and designated ORV routes, alternative F would involve the construction of new parking areas, pedestrian access trails, ORV ramps, and improvements and additions to the interdunal road system. A seasonal night-driving restriction would be established from 9:00 p.m. to 7:00 a.m. during turtle nesting season although areas with no turtle nests could open to night driving from September 16 through November 15. Alternative F would provide for an alternative transportation study and would encourage the establishment of a beach shuttle or water taxi.

Based in part on public and agency comments on the draft plan/EIS, this alternative has been modified within the range of alternatives described in the draft plan/EIS.

Table ES-2 indicates the designated routes and areas under alternatives A, B, C, D, and E. Table ES-2A indicates the designated routes and areas under alternative F.

## **ENVIRONMENTAL CONSEQUENCES**

Impacts of the alternatives were assessed in accordance with NPS Director's Order 12 and Handbook: Conservation Planning, Environmental Impact Analysis and Decision-Making. This handbook requires that impacts on park resources be analyzed in terms of their context, duration, and intensity. The analysis provides the public and decision-makers with an understanding of the implications of ORV management actions in the short and long term, cumulatively, and within context, based on an understanding and interpretation by resource professionals and specialists.

For each impact topic, methods were identified to measure the change in the Seashore's resources that would occur with the implementation of each management alternative. Thresholds were established for each impact topic to help understand the severity and magnitude of changes in resource conditions, both adverse and beneficial.

Each management alternative was compared to baselines to determine the context, duration, and intensity of resource impacts. The baselines are the conditions that resulted from management of ORVs under the management frameworks in place during the planning process for this plan/EIS. The baselines are represented by alternatives A and B.

Table ES-5 summarizes the results of the impact analysis for the impact topics that were assessed.

Intentionally Left Blank

TABLE ES-2. OFF-ROAD VEHICLE ROUTES AND AREAS – ALTERNATIVES A, B, C, D, AND E

Oceanside Location	Mileage <sup>a</sup>	Alternatives A and B: No Action	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management
<b>Bodie Island (north to south)</b> Ramp 1 to north end of Coquina Beach	0.9	OPEN <sup>b</sup> Seasonally closed May 15 to Sep 15 (longstanding safety closure).	ORV route—Mar 15 to Oct 14 VFA—Oct 15 to Mar 14	X	X Parking at ramp 1 expanded.
North end of Coquina Beach to 0.5 mile south of Coquina	0.8	OPEN <sup>b</sup> Seasonally closed May 15 to Sep 15 (longstanding safety closure). South of ramp 2 at Coquina Beach open seasonally.	X Ramp 2 relocated approx. 0.5 mile south of Coquina Beach.	X Ramp 2 relocated approx. 0.5 mile south of Coquina Beach.	X Ramp 2 relocated approx. 0.5 mile south of Coquina Beach. Parking at Coquina Beach expanded.
0.5 mile south of Coquina to 0.2 mile south of ramp 4 (Includes beach in front of Oregon Inlet Campground. If Bonner Bridge construction closes ramp 4, new ramp 3 will be constructed north of campground and day-use parking and trailhead near campground will be provided.)	2.1	OPEN YR <sup>b</sup>	ORV route YR	ORV route YR	ORV route YR ORV pass-through zone established on upper beach in front of campground when campground is open.
0.2 mile south of ramp 4 to inlet to southwest edge of Bait Pond (Species Management Area)	1.9	OPEN YR <sup>b</sup>	ORV route—Oct 15 to Mar 14 VFA—Mar 15 to Oct 14 Area closed to ORVs from March 15 to October 14. When prenesting area is established, a pedestrian access corridor would be allowed along ocean shoreline to the inlet. When shorebird breeding activity is observed, standard buffers would apply, which depending upon the circumstances could close the access corridor. (ML2)	X (ML1)	ORV route YR With expected limited access Mar 15 to Aug 31 When prenesting area is established, ORV corridor with pass-through zone would be allowed along ocean shoreline to the inlet. When shorebird breeding activity is observed, standard buffers would apply, which depending upon the circumstances could close the access corridor. Pedestrian trail to inlet from new parking near campground established. Trail subject to resource closures. NPS would allow water taxi service to spit from Oregon Inlet Fishing Center, subject to designated landing zone and to resource closures. (ML2)
<b>Hatteras Island (north to south)</b> Rodanthe—Waves—Salvo to ramp 23 (includes Tri-Village beaches)	5.3	OPEN <sup>b</sup> Seasonally closed May 15 to Sep 15.	ORV route—Oct 15 to Mar 14 VFA—Mar 15 to Oct 14 Parking at ramp 23 expanded.	X	ORV route—Nov 1 to Mar 31 VFA—Apr 1 to Oct 31 Parking at ramp 23 expanded.
Ramp 23 to ramp 27	4.3	OPEN YR <sup>b</sup>	ORV route YR	ORV route YR	ORV route YR One new ramp with parking established at 24 or 26.
Ramp 27 to ramp 30 (Species Management Area)	2.2	OPEN YR <sup>b</sup>	ORV route—Oct 15 to Mar 14 VFA—Mar 15 to Oct 14 (ML1)	X (ML1)	X (ML1)
Ramp 30 to (new) ramp 32.5	2.5	OPEN YR <sup>b</sup>	ORV route YR New ramp with parking established at 32.5.	ORV route YR New ramp established at 32.5.	ORV route YR New ramp with parking established at 32.5.
(New) ramp 32.5 to ramp 34 (Species Management Area)	1.8	OPEN YR <sup>b</sup>	ORV route—Oct 15 to Mar 14 VFA—Mar 15 to Oct 14 (ML1)	X (ML1)	ORV route—Sep 1 to Mar 14 VFA—Mar 15 to Aug 31 (ML1)
Ramp 34 to ramp 38 (includes Avon Village Beach)	3.9	OPEN <sup>b</sup> Seasonally closed May 15 to Sep 15.	ORV route—Oct 15 to Mar 14 VFA—Mar 15 to Oct 14	X	ORV route—Nov 1 to Mar 31 VFA—Apr 1 to Oct 31 Parking at ramp 34 expanded.
Ramp 38 to approx. 1.7 miles south	1.7	OPEN YR <sup>b</sup>	ORV route YR	ORV route YR	ORV route YR Parking at ramp 38 expanded.
Approximately 1.7 miles south of ramp 38 (i.e., Haulover) to Buxton line (Species Management Area)	2.0	OPEN YR <sup>b</sup> (Current 3.8-mile safety closure from 1.8 miles south of ramp 38 to 0.4 mile north of ramp 43.)	ORV route—Oct 15 to Mar 14 VFA—Mar 15 to Oct 14 (ML1)	X (ML1)	ORV route—Sep 1 to Mar 14 VFA—Mar 15 to Aug 31 (ML1)
Buxton Village Beach to 0.4 mile north of ramp 43	1.9	OPEN <sup>b</sup> Seasonally closed May 15 to Sep 15 (longstanding safety closure).	X NPS or Dare County to establish new parking at old Coast Guard Station site (following Coast Guard clean-up of the site).	X	ORV route—Nov 1 to Mar 31 VFA—Apr 1 to Oct 31 NPS or Dare County to establish new parking at old Coast Guard Station site (following Coast Guard clean-up of the site).

Oceanside Location	Mileage <sup>a</sup>	Alternatives A and B: No Action	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management
0.4 mile north of ramp 43 to ramp 43	0.4	OPEN <sup>b</sup> Subject to seasonal closure May 15 to Sep 15.	ORV route—Oct 15 to Mar 14 VFA—Mar 15 to Oct 14	X	ORV route—Mar 15 to Aug 31 VFA—Sep 1 to Mar 14 Open to ORVs only when east side of Cape Point is closed.

0.5 mile southwest of ramp 72 to inlet (Species Management Area)	1.3	OPEN YR <sup>b</sup>	ORV route—Oct 15 to Mar 14 VFA—Mar 15 to Oct 14 When prenesting area is established, a pedestrian access corridor would be allowed along ocean shoreline to the inlet. When shorebird breeding activity is observed, standard buffers would apply, which depending upon the circumstances could close the access corridor. (ML2)	X (ML1)	ORV route YR With expected limited access Mar 15 to Aug 31 When prenesting area is established, ORV access corridor with pass-through zone would be allowed along ocean shoreline to the inlet. When shorebird breeding activity is observed, standard buffers would apply, which depending upon the circumstances could close the access corridor. NPS would also allow water taxi service to spit from Silver Lake, subject to designated landing zone and resource closures. (ML2)
Inlet shoreline along South Point	1.0	OPEN YR <sup>b</sup>	X	X	X

Oceanside Location	Mileage <sup>a</sup>	Alternatives A and B: No Action	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management
--------------------	----------------------	---------------------------------	------------------------------------	---	---

NOTES: Details on soundside access provided in table 8. Due to updated base mapping, the shape of the inlets and spits was updated for alternative F maps, resulting in a slight difference in mileage between alternative F and the other alternatives (see table 7-1).

<sup>a</sup> All mileages are approximate.

<sup>b</sup> Area(s) open to ORV use, except when resource, seasonal, or safety closures are in effect.

Designated ORV routes and areas (ORV route = ORV permitted, X = VFA (vehicle-free area); YR = year-round).

All ORV routes and areas subject to temporary resource closures.

**Species Management Areas (SMAs):** ML1 and ML2 are the two proposed strategies for species management. See table 10 for a detailed description of these strategies. All areas outside of designated SMAs would be managed under ML1 protocols.

(ML1) Once prenesting closures are established, ORV and pedestrian access would be prohibited until breeding activity is completed.

(ML2) Once prenesting closures are established, ORV or pedestrian access corridor(s) and/or boat landing areas (as indicated in the respective alternatives) would be permitted. Upon the first observation of breeding activity, similar ML2 buffers would apply, which depending upon the circumstances may close the access corridor.

Designated ORV Route Mileage (Approximate) <sup>f</sup>	Alternative A <sup>c</sup>	Alternative B <sup>c</sup>	Alternative C	Alternative D	Alternative E
Designated as ORV route YR	49.4	50.1	27.4	27.2	31.6
Designated for seasonal ORV use	17.9	16.2	27.0	0	20.2
Designated as Vehicle-Free Area YR (X) <sup>e</sup>	0 <sup>d</sup>	1.0	12.9	40.1	15.5
Total	67.3	67.3	67.3	67.3	67.3

<sup>c</sup> Routes under alternatives A and B have not been officially designated for ORV use. The mileages shown in this table are based on areas open to ORV use under the Interim Protected Species Management Strategy and the consent decree.

<sup>d</sup> Does not include mileage closed for safety reasons.

<sup>e</sup> Miles designated as closed to ORV year-round do not include the 12 miles at Pea Island National Wildlife Refuge where vehicles are not permitted. Including the mileage of Pea Island, areas designated closed to ORVs year-round would be as follows: Alternative C = 24.9; Alternative D = 52.1; Alternative E = 27.5

TABLE ES-2A. OFF-ROAD VEHICLE ROUTES AND AREAS – ALTERNATIVE F

Oceanside Location	Mileage	Alternative F: Preferred Alternative
<b>Bodie Island (north to south)</b> Ramp 1 to 0.5 miles south of Coquina Beach	1.7	X Parking at old Bodie Island Coast Guard Station site (use existing asphalt-paved parking area, or resurface using pervious material after site is used as a potential staging area for proposed widening and repaving of NC12)
0.5 mile south of Coquina to 0.2 mile south of ramp 4	2.1	ORV route YR New ramp with parking at 2.5.
0.2 mile south of ramp 4 to southeast corner of Bodie Island spit	1.1	ORV route—Sep 15 to Mar 14 X—Mar 15 to Sep 14 New parking area and trailhead near ramp 4, with pedestrian trail to the “flats” on the northeast side of the Bait Pond.
Southeast corner of Bodie Island spit along inlet shoreline to southwest edge of Bait Pond (near bridge)	0.8	X

0.1 mile south of Rodanthe Pier—Waves—Salvo to ramp 23	3.7	ORV route—Nov 1 to Mar 31 X—Apr 1 to Oct 31
Ramp 23 to 1.5 miles south of ramp 23	1.5	X New parking 1.0 mile south of ramp 23.
1.5 miles south of ramp 23 to ramp 27	2.8	ORV route YR. New ramp with parking at 25.5.
Ramp 27 to ramp 30	2.2	X New parking near soundside ramp 48.
Ramp 30 to (new) ramp 32.5	2.3	ORV route YR
(New) ramp 32.5 to ramp 34	2.0	X New parking near soundside ramp 52.
Ramp 34 to ramp 38 (includes Avon Village Beach)	3.9	ORV route—Nov 1 to Mar 31 X—Apr 1 to Oct 31
Ramp 38 to 1.5 miles south of ramp 38 (i.e., Haulover)	1.5	ORV route YR
1.5 miles south of ramp 38 (i.e., Haulover) to 0.4 mile north of ramp 43 (includes Buxton)	4.1	X New parking area on west side of highway at or near Kite Point New parking area on west side of highway at or near soundside ramp 60 NPS or Dare County to establish new parking at old Coast Guard Station site (following Coast Guard clean-up of the site) New parking area at Loran Road
0.4 mile north of ramp 43 to Cape Point to 0.3 miles west of the hook	2.1	ORV route YR Existing interdunal road Cape Point south of Salt Pond at the narrows
0.3 mile west of the hook (Cape Point) to 1.7 miles west of ramp 45	2.8	X
1.7 miles west of ramp 45 to the east Frisco boundary (includes ramp 49)	2.9	ORV route YR Interdunal road extended from ramp 45 to ramp 49, with new ramp 47.5.
Frisco Village Beach (east village boundary to west boundary)	1.1	ORV route—Nov 1 to Mar 31 X—Apr 1 to Oct 31
Sandy Bay / Frisco day use area (west Frisco boundary to east Hatteras Village boundary)	1.4	X

Oceanside Location	Mileage	Alternative F: Preferred Alternative
Hatteras Village Beach (east boundary to ramp 55)	2.2	ORV route—Nov 1 to Mar 31 X—Apr 1 to Oct 31
Ramp 55 along ocean beach to Bone Road	1.6	ORV route YR
Bone Road to Hatteras Inlet, along inlet shoreline to Spur Road	1.0	X
Pole Road from NC-12 to Spur Road	2.3	ORV route YR
Cable Crossing route (from Pole Road to sound)	0.2	ORV route YR
Spur Road route (from Pole Road to sound)	0.4	ORV route YR
(New) interdunal road from eastern portion of Spur Road west toward inlet	0.2	ORV route—Sep 15 to Mar 14 X—Mar 15 to Sep 14
<b>Ocracoke Island (north to south)</b> Inlet to (new) ramp 59.5	1.6	X
(New) ramp 59.5 to (new) ramp 63	3.9	ORV route YR New parking area on west/north side of the highway at or near the entrance to Barrow Pit Road
(New) ramp 63 to 1.0 mile northeast of ramp 67	2.5	X
1.0 mile northeast of ramp 67 to 0.5 mile northeast of ramp 68	1.7	ORV route YR
0.5 mile northeast of ramp 68 to ramp 68 (Ocracoke Campground area)	0.5	ORV route—Nov 1 to Mar 31 X—Apr 1 to Oct 31
Ramp 68 to 0.4 miles northeast of ramp 70 (includes Ocracoke Day Use area)	2.2	X
0.4 mile northeast of ramp 70 to Ocracoke Inlet (includes ramp 72)	4.1	ORV route YR
Inlet shoreline along South Point	1.0	X

NOTES: Details on soundside access provided in table 8. Parking areas indicated above would be accessible to 2-wheel drive vehicles.

All mileages are approximate.

Designated ORV routes and areas (ORV route = ORV use permitted; X = VFA (vehicle-free area); YR = year-round).

ORV routes are subject to safety closures and temporary resource closures. VFAs are subject to temporary resource closures.

Designated ORV Route Mileage (Approximate <sup>a</sup> )	Alternative F
Designated as ORV Route YR	27.9
Designated for seasonal ORV use	12.7
Designated as vehicle-free area YR (X) <sup>b</sup>	26.4
Total	67 <sup>c</sup>

<sup>a</sup> All mileages are approximate

<sup>b</sup> Miles designated as vehicle-free area year-round does not include the 12-miles at Pea Island National Wildlife Refuge where vehicles are not permitted. Including the mileage of Pea Island, areas designated closed to ORVs year-round would equal 38.4 miles under alternative F.

<sup>c</sup> Due to updated base mapping, the shapes of the inlets and spits were updated for maps of alternative F, resulting in a slight difference in mileage between alternative F and the other alternatives.

**TABLE ES-3. SUMMARY OF ALTERNATIVE ELEMENTS**

This matrix is designed to display differences among alternatives; therefore, actions common to all alternatives are not included in it. Refer to the “Elements Common to All Alternatives” section, which begins on page 56 of chapter 2.

Alternative A: No Action— Continuation of Management under the Interim Strategy	Alternative B: No Action— Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>ORV Routes, Use Areas, and Corridors</b>					
<p><b>ORV use areas:</b> All areas of the Seashore are potentially open to ORV access, except when closed as described in Superintendent’s Order 7. Visitors accessing the Seashore by ORV must drive only on marked ORV routes and must comply with posted restrictions. Refer to table 7.</p> <p><b>ORV corridors:</b> The ORV corridor on the ocean beach is marked by posts placed approx. 150 feet landward from the average, normal high tide line, or if less than 150 feet of space is available, at the vegetation or the toe of the remnant dune line, except as noted in the Interim Strategy. The corridor width will fluctuate over time due to the dynamic nature of beach and surf.</p>	<p><b>ORV use areas:</b> Same as alternative A.</p> <p><b>ORV corridors:</b> Same as alternative A, except: Mar 15 to Nov 30: In all locations not in front of the villages that are open to ORV use, NPS shall provide an ORV-free zone in the ocean backshore at least 10 meters wide, wherever there is sufficient beach width to allow an ORV corridor of at least 20 meters above the mean high tide line.</p>	<p><b>ORV routes:</b> ORV access would be prohibited in all areas of the Seashore except where an ORV route is specifically designated. An <i>ORV route</i> is a designated location, typically linear in nature (e.g., from point A to point B), where ORV travel may be authorized by the Superintendent, but which may be temporarily closed to ORV use to protect Seashore resources, provide for visitor safety, or prevent user conflicts. Refer to table 7.</p> <p><b>ORV corridors:</b> An <i>ORV corridor</i> is the actual physical demarcation of the ORV route in the field. The ORV corridor on the ocean beach would be marked by posts seaward of the toe of dune or vegetation line to the high tide line (the seaward side of the corridor would not be posted). ORV routes through vegetated areas, such as interdunal roads and ramps, would be posted on both sides of the corridor.</p> <p><b>Seasonally designated ORV routes:</b> These would occur as indicated in table 7.</p>	<p><b>ORV routes:</b> ORV access would be prohibited in all areas of the Seashore except where an ORV route is specifically designated. The definition of ORV route is same as for alternative C.</p> <p><b>ORV corridors:</b> Same as alternative C.</p> <p><b>Seasonally designated ORV routes:</b> No seasonal designations under this alternative.</p>	<p><b>ORV routes:</b> ORV access would be prohibited in all areas of the Seashore except where an ORV route is specifically designated. The definition of ORV route is same as for alternative C.</p> <p><b>ORV corridors:</b> Same as alternative C, except: Mar 15 to Aug 31: Where the ocean beach is at least 30 meters wide above the high tide line, the corridor would be posted 10 meters seaward of the toe of the dune to provide an ocean backshore closure.</p> <p><b>Seasonally designated ORV routes:</b> These would occur as indicated in table 7.</p>	<p><b>ORV routes:</b> ORV access would be prohibited in all areas of the Seashore except where an ORV route is specifically designated. The definition of ORV route is same as for alternative C.</p> <p><b>ORV corridors:</b> Same as alternative C, except: Year-round: Where the ocean beach is at least 30 meters wide above the high tide line, the corridor would be posted 10 meters seaward of the toe of the dune to provide an ocean backshore closure.</p> <p><b>Seasonally designated ORV routes:</b> These would occur as indicated in table 7-1.</p>

<b>ORV Access</b>					
<p><b>Oceanside access:</b> ORV access is provided via 17 oceanside ramps and access points located off NC-12. Ramps are numbered and identified on the Seashore’s ORV route map as official vehicle access routes. Seashore staff maintains ramps and signage.</p>	<p><b>Oceanside access:</b> Same as alternative A.</p>	<p><b>Oceanside access:</b> To provide access to the designated ORV routes and VFAs in addition to the existing ramps, which would be maintained, new or improved ramps would be developed as identified in table 7. Toilet facilities and trash receptacles would be provided at high use locations.</p>	<p><b>Oceanside access:</b> Same as alternative C.</p>	<p><b>Oceanside access:</b> Same as alternative C.</p>	<p><b>Oceanside access:</b> To provide access to designated ORV routes, VFAs, and existing ramps, new ramps would be developed as identified in table 7-1.</p>
<p><b>Soundside access:</b> ORV access is provided via 18 soundside access points located off NC-12. Seashore staff maintains ramps and signage.</p>	<p><b>Soundside access:</b> Same as alternative A.</p>	<p><b>Soundside access:</b> Existing soundside ramps would be designated as ORV routes and would remain open with sufficient maintenance to provide clear passage. Signage/posts would be installed at the primitive parking areas and boat launch areas to prevent damage to vegetation and other soundside resources.</p>	<p><b>Soundside access:</b> Same as alternative A.</p>	<p><b>Soundside access:</b> Soundside ramps to designated boat launch areas and Pole Road access to the sound via Cable Crossing and Spur Road would remain open. The remaining soundside ramps would be closed to ORV use and small parking areas would be constructed to provide pedestrian access to the water, except: Existing Ocracoke Island access points north of village would remain open to commercial fishermen. Signage/posts would be installed at the parking areas and boat launch areas to prevent damage to vegetation and other soundside resources.</p>	<p><b>Soundside access:</b> Existing off-road soundside areas would be designated as ORV routes and would remain open with sufficient maintenance to provide clear passage. Signage/posts would be installed at the primitive parking areas and boat launch areas to prevent damage to vegetation and other soundside resources. Seasonal soundside access on Ocracoke Island (open Sept 15 – March 14):  <ul style="list-style-type: none"> <li>• ORV route 0.6 mile south of ramp 72 from the beach route to a pedestrian trail to Pamlico Sound.</li> </ul>                     ORV route at the north end of South Point spit from the beach route to Pamlico Sound.</p>

<b>Ramp Characteristics</b>					
Ramp width and construction details vary. Current practice is to use shell/clay base material to provide firm driving surface where ramps cross dune line.	Same as alternative A.	<b>Ramps would be two lanes wide with shell/clay base and have:</b> <ul style="list-style-type: none"> <li>Standard regulatory signs and information boards at all ramps.</li> <li>Gates at all ramps and access points.</li> <li>Designated “air down” area with hardened surface (e.g., shell/clay base).</li> </ul>	Same as alternative C.	Same as alternative C.	– Same as alternative C.
<b>Permit Requirements</b>					
No permit required.	Night-driving permit required for ORV use from 10:00 p.m. to 6:00 a.m. Sep 16 to Nov 15.	ORV permit required.	Same as alternative C.	Same as alternative C.	Same as alternative C.
<b>Permit Distribution</b>					
N/A	Available in person at various locations and online.	Available in person at designated permit issuing stations and online.	Same as alternative C.	Same as alternative C.	Available in person at designated NPS permit issuing stations.
<b>Permit Issuance Requirements</b>					
N/A	ORV owner must sign permit to acknowledge understanding of the rules and must carry permit when beach driving during the restricted period.	ORV owners must complete a short education program in person or online and pass a basic knowledge test. Owners would sign for their permits to acknowledge understanding of the rules and regulations governing ORV use at the Seashore.	ORV owners must read an information brochure and sign the permit to acknowledge understanding of the rules and regulations governing ORV use at the Seashore.	Same as alternative C.	ORV owners must complete a short education program in person and sign for the permit to acknowledge understanding of the rules and regulations governing ORV use at the Seashore.
<b>Permit Types</b>					
N/A	Night-driving permit for Sep 16 to Nov 15.	Annual ORV permits would be valid for 12 months from date of purchase.	Annual ORV permits would be valid for the calendar year.	Weekly (7-day) and annual (12-month) ORV permits would be valid from date of purchase. Permits would include night-driving component for September 16 to November 15. In addition, a separate permit would be required for the following activities: <ul style="list-style-type: none"> <li>Park-and-stay overnight.</li> <li>Self-contained vehicle (SCV) camping.</li> </ul>	7-day ORV permits would be valid from date of purchase. Annual ORV permits would be valid for the calendar year. Permits would include night-driving component for September 16 to November 15.
<b>Permit Number Limits</b>					
N/A	No limit on night-driving permits.	No limit on ORV permits.	Same as alternative C.	Same as alternative C, except: <ul style="list-style-type: none"> <li>Use limits would be established for park-and-stay and SCV camping.</li> <li>Use limits would be subject to periodic review.</li> </ul>	Same as alternative C.

Alternative A: No Action— Continuation of Management under the Interim Strategy	Alternative B: No Action— Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Permit Fees</b>					
N/A	None	ORV permit fee would be based on cost recovery as described in NPS Director’s Order and Reference Manual 53.	Same as alternative C, except: <ul style="list-style-type: none"> <li>Amount of fee would be lower than alternative C due to decreased management costs under this alternative.</li> </ul>	Same as alternative C, except: <ul style="list-style-type: none"> <li>Fee for weekly ORV permit would be less than fee for annual permit.</li> <li>Fees for park-and-stay and SCV permits would be determined separately.</li> </ul>	Same as alternative C, except: <ul style="list-style-type: none"> <li>Fee for 7-day ORV permit would be less than fee for annual permit.</li> </ul>
<b>Permit Form</b>					
N/A	Night-driving permit is an informational brochure that the user signs and places on dash of vehicle.	ORV permit would be affixed to vehicle in a manner approved by the NPS.	Same as alternative C.	Same as alternative C.	Same as alternative C.
<b>Permit Revocation</b>					
N/A	Night-driving permit may be revoked for violation of applicable park regulations or terms and conditions of the permit.	ORV permit may be revoked for violation of applicable park regulations or terms and conditions of the permit.	Same as alternative C.	Same as alternative C.	Same as alternative C.
<b>Beach Parking</b>					
Parking within routes is allowed in any configuration, as long as parked vehicles do not obstruct traffic.	Same as alternative A.	Same as alternative A.	Parking within ORV routes is allowed, but only one vehicle deep. Stacking of vehicles in more than one row would be prohibited.	Same as alternative A.	Parking within ORV routes is allowed, but only one vehicle deep, as long as vehicles do not obstruct two-way traffic. Stacking of vehicles in more than one row would be prohibited.
<b>Vehicle Carrying Capacity Determination</b>					
Vehicle carrying capacity would not be determined.	Same as alternative A.	Carrying capacity would be a “peak use limit” determined for all areas based on the linear feet of beachfront and the following physical space requirements (“mile” refers to miles of beach open to ORV use): <p><b>Bodie Island District:</b></p> <ul style="list-style-type: none"> <li>260 vehicles/mile (20 feet/vehicle).</li> </ul> <p><b>Hatteras Island District:</b></p> <ul style="list-style-type: none"> <li>260 vehicles/mile (20 feet/vehicle).</li> </ul> <p><b>Ocracoke Island District:</b></p> <ul style="list-style-type: none"> <li>175 vehicles/mile (30 feet/vehicle).</li> </ul> Temporary exceptions to carrying-capacity limits may be approved for short-term events operating under a special use permit. Carrying-capacity criteria would be subject to periodic review.	Carrying capacity would be addressed solely by the beach parking restriction described in the row above.	Same as alternative C, except: <p><b>Hatteras Island District:</b></p> <ul style="list-style-type: none"> <li>Cape Point: 400 vehicles allowed within a 1 mile area centered on Cape Point.</li> </ul>	The maximum number of vehicles allowed on any particular ORV route is the linear distance of the route divided by 6 meters (20 feet) per vehicle (i.e., the equivalent of 260 vehicles per mile).

Alternative A: No Action— Continuation of Management under the Interim Strategy	Alternative B: No Action— Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>ORV Characteristic Requirements</b>					
All vehicles operating in all areas of the Seashore must have valid vehicle registration, insurance, and license plate. Vehicles must be street legal. All-terrain vehicles (ATVs) are prohibited from beach driving.	Same as alternative A.	Off-road Vehicle characteristics: <ul style="list-style-type: none"> <li>• All vehicles must be registered, licensed, and insured for highway use and must comply with state inspection regulations within the state, country, or province where the vehicle is registered</li> <li>• Four-wheel-drive vehicles are recommended.</li> <li>• Two-wheel-drive vehicles are allowed.</li> <li>• Motorcycles and ATVs are prohibited.</li> <li>• There is a three-axle maximum for vehicles (this is the axle maximum for the powered vehicle only and does not include the additional number of axles on towed trailers).</li> <li>• Any trailers are limited to no more than two axles.</li> <li>• The maximum vehicle length is 30 feet (this is the maximum length for the powered vehicle and does not include the additional length of a towed trailer).</li> <li>• Tires must be U.S. Dept. of Transportation-listed or approved.</li> </ul>	Same as alternative C.	Same as alternative C, except: <ul style="list-style-type: none"> <li>• Motorcycles would be prohibited on ocean beaches, but allowed on soundside access areas where ORVs are allowed.</li> </ul>	Off-road vehicle characteristics: <ul style="list-style-type: none"> <li>• All vehicles must be registered, licensed, and insured for highway use and must comply with state inspection regulations within the state, country, or province where the vehicle is registered.</li> <li>• Four-wheel-drive vehicles are recommended.</li> <li>• Two-wheel-drive vehicles are allowed.</li> <li>• Motorcycles, ATVs, and UTVs are prohibited.</li> <li>• The vehicle must have no more than two axles.</li> <li>• Towed boat trailers are allowed and must have no more than two axles. Travel trailers (i.e., camping trailers) are prohibited.</li> <li>• Vehicle tires must be U.S. Department of Transportation-listed or approved.</li> </ul>
<b>Equipment Requirements</b>					
None	Same as alternative A.	<b>Equipment requirements:</b> <ul style="list-style-type: none"> <li>• All vehicles shall contain a low-pressure tire gauge, shovel, jack, and jack stand.</li> <li>• A full-sized spare tire, first-aid kit, fire extinguisher, trash bag or container, flashlight (if night driving), and tow strap are recommended.</li> </ul>	Same as alternative C.	Same as alternative C.	Same as alternative C.
<b>Tire Pressure</b>					
Recommend air down of tires before driving on the beach.	Same as alternative A.	When driving on designated routes, tire pressure must be lowered sufficiently to maintain adequate traction within the posted speed limit. Tire pressure of 20 psi is <i>recommended</i> for most vehicles. The softer the sand, the lower the pressure needed. Re-inflate tires to normal pressure as soon as possible after vehicle returns to paved roads.	Same as alternative C.	Same as alternative C.	Same as alternative C.

Alternative A: No Action— Continuation of Management under the Interim Strategy	Alternative B: No Action— Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Speed Limit</b>					
Speed limit is 25 mph (unless otherwise posted) on park beaches for public and private vehicles. Speed limit is 10 mph when ORV corridor is less than 100 feet wide. Speed limit in front of villages during off season (Sep 16 to May 14) on park beaches posted at 10 mph. <b>Emergency vehicles exempt when responding to a call.</b>	May 15 to Sep 15: Speed limit is 15 mph (unless otherwise posted). Sep 16 to May 14: Speed limit is 25 mph (unless otherwise posted).	Speed limit is 15 mph (unless otherwise posted). <b>Emergency vehicles exempt when responding to a call.</b>	<b>Same as alternative C.</b>	<b>Same as alternative C.</b>	<b>Same as alternative C.</b>
<b>Essential Vehicles</b>					
Essential vehicles are allowed in VFAs and within resource closures subject to guidelines in the “Essential Vehicles” section of appendix G of the USFWS <i>Piping Plover, Atlantic Coast Population, Revised Recovery Plan</i> . To the extent practicable, emergency response vehicle operators will consult with trained resource management staff regarding protected species before driving into or through resource closures; however, prior consultation may not always be practical.	Same as alternative A.	Same as alternative A.	Same as alternative A.	Same as alternative A.	Same as alternative A.
<b>VFAs</b>					
None designated. ORVs are temporarily prohibited in seasonal (village) closures, safety closures, administrative closures, and resource closures, including some areas that have been closed to ORV use for many years.	Same as alternative A.	VFAs would be designated as indicated in table 7.	VFAs would be designated as indicated in table 7.	VFAs would be designated as indicated in table 7.	VFAs would be designated as indicated in table 7-1.
<b>Resource Education</b>					
Information is available to the general public through the park website, newspaper, information brochures, and interpretive programs. However, there is no targeted education program for beach users.	Same as alternative A, except: <ul style="list-style-type: none"> <li>• Night-driving permit has basic education component.</li> <li>• Protected species information is available at ORV access points.</li> <li>• There is a 24-hour citizen phone line.</li> <li>• The beach access brochure is to be redesigned.</li> </ul>	General information would remain available as described in alternative A. There would be a new required education program for ORV users, as described under ORV Permit Issuance Requirements.	<b>Same as alternative C.</b>	<b>Same as alternative C.</b>	<b>Same as alternative C, plus:</b> <ul style="list-style-type: none"> <li>• There would be a new voluntary resource education program targeted toward pedestrian beach users.</li> </ul>

Alternative A: No Action— Continuation of Management under the Interim Strategy	Alternative B: No Action— Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Temporary ORV Use of VFAs</b>					
<p>Beach access would be provided through the issuance of special use permits for areas in front of the villages to allow ORVs to transport visitors with disabilities to the beach and then return the vehicle back to the street.</p>	<p>Beach access would be provided through the issuance of special use permits for areas in front of the villages to allow ORVs to transport visitors with disabilities to the beach and then return the vehicle back to the street.</p>	<p>Under the terms and conditions of a special use permit, the Superintendent could authorize the following:</p> <ul style="list-style-type: none"> <li>• Beach access would be provided through the issuance of special use permits for areas in front of the villages to allow ORVs to transport visitors with disabilities to the beach and then return the vehicle back to the street.</li> <li>• Temporary emergency ORV use of VFAs if needed to bypass sections of NC-12 that are closed for repairs. This could apply to all vehicles, including private vehicles, and would require a special use permit during the temporary emergency situation.</li> <li>• Temporary non-emergency ORV use of VFAs traditionally used for fishing tournaments that were established prior to Jan 1, 2009.</li> <li>• Temporary non-emergency ORV use of VFAs in front of villages to transport mobility-impaired individuals to join their family or friends on an open beach that is otherwise closed to ORVs. ORV use would be limited to the shortest, most direct distance between the nearest designated ORV route and the location of the gathering.</li> </ul> <p>Temporary non-emergency use by <i>nonessential</i> vehicles would not be permitted within resource closures.</p>	<p>Same as alternative A.</p>	<p>Same as alternative C.</p>	<p>The superintendent may issue a special use permit for temporary off-road vehicle use to:</p> <ul style="list-style-type: none"> <li>• Authorize the North Carolina Department of Transportation to use Seashore beaches as a public way when necessary to by-pass sections of NC Highway 12 that are impassible or closed for repairs.</li> <li>• Allow participants in a regularly-scheduled fishing tournament to drive in an area not designated for off-road use, if off-road use was allowed in that area for that tournament before January 1, 2009.</li> <li>• Allow vehicular transport of mobility-impaired individuals to a predetermined location in a designated VFA in front of villages via the shortest most direct distance from the nearest designated ORV route or Seashore road; the vehicle must return to the designated ORV route or Seashore road immediately after the transport.</li> </ul> <p>Temporary non-emergency use by <i>nonessential</i> vehicles would not be permitted within resource closure.</p>
<b>Parking Areas for Access to VFAs</b>					
<p>Parking is currently provided in 32 park-maintained parking lots throughout the Seashore, totaling approx. 1,000 spaces.</p>	<p>Same as alternative A.</p>	<p>New or expanded parking would be established to support pedestrian access to VFAs as identified in table 7. NPS would use environmentally appropriate design standards to minimize stormwater runoff and other resource impacts. Toilet facilities and trash receptacles would be provided at high-use locations.</p>	<p>Same as alternative C.</p>	<p>Same as alternative C.</p>	<p>Same as alternative C, except as identified in table 7-1.</p>

Alternative A: No Action— Continuation of Management under the Interim Strategy	Alternative B: No Action— Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Alternative Transportation</b>					
None	Same as alternative A.	NPS would consider applications for commercial use authorization to offer beach shuttle services.	Same as alternative A.	Same as alternative C, plus: <ul style="list-style-type: none"> <li>• NPS would designate and post boat landing zones (drop-off) near the inlet at Bodie Island Spit and South Point Ocracoke that could be used to drop off pedestrians if/when the inlet shoreline is not otherwise closed to protect Seashore resources. NPS would encourage a commercial water shuttle service for this purpose; however, the drop-off points would be subject to closure on short notice if needed to protect Seashore resources.</li> </ul>	NPS would consider applications for commercial use authorizations to offer beach and water shuttle services. NPS would apply for funding to conduct an alternative transportation study to evaluate the feasibility of alternative forms of transportation to popular sites, such as inlets and Cape Point.

Alternative A: No Action— Continuation of Management under the Interim Strategy	Alternative B: No Action— Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Camping and Nighttime Beach Use</b>					
<p>Per 36 CFR 2.10: Camping<sup>a</sup> is prohibited except in designated areas. In the Superintendent's Compendium, camping is prohibited on Seashore beaches. In areas open to ORV use, ORVs are allowed on the beach overnight if someone associated with the vehicle is actively fishing.</p> <p><sup>a</sup>Camping is defined in 36 CFR 1.4 as the erecting of a tent or shelter of natural or synthetic material, preparing a sleeping bag or other bedding material for use, parking of a motor vehicle, motor home, or trailer, or mooring of a vessel for the apparent purpose of overnight occupancy.</p>	<p>Same as alternative A, plus:</p> <ul style="list-style-type: none"> <li>Nighttime use of ORVs is seasonally restricted as described under the Hours of Allowable ORV Operation section.</li> </ul>	<p>Same as alternative B, plus:</p> <ul style="list-style-type: none"> <li>Unattended beach equipment (e.g., chairs, canopies, volleyball nets, watersports gear) is prohibited on the Seashore at night. Turtle patrol and law enforcement will tag equipment found at night. Owners have 24 hours to remove equipment before it is removed by NPS staff.</li> </ul>	<p>Same as alternative C.</p>	<p>Same as alternative C, plus: SCV camping would be authorized as follows:</p> <ul style="list-style-type: none"> <li>The following campgrounds and use limits would be designated for SCV camping from Nov 1 to Mar 31: Oregon Inlet—100 spaces; Cape Point—100 spaces; and Ocracoke—50 spaces. Use limits would be established in the Superintendent's Compendium and subject to periodic review.</li> <li>SCV permits would be required, in addition to an ORV permit for beach driving, and would be available in weekly or seasonal increments.</li> <li>There would be a 7-consecutive-day- / 6-night-stay limit during any one visit and a limit of one visit per month.</li> <li>SCVs would be required to have a self-contained toilet and a separate, permanently installed holding tank for both black and grey water, each with a min. capacity of 3 days' waste.</li> <li>Holding tanks must be dumped at an appropriate facility every 72 hours during a visit.</li> </ul> <p>Between May 1 and September 16, ORV park-and-stay overnight would be allowed with a permit at selected spits and points, if not otherwise closed to protect resources. The following park-and-stay use limits would be established: Inlet spits—15 vehicles each; Cape Point and South Point Ocracoke—25 vehicles each.</p> <p>Park-and-stay use limits and hours of night-driving prohibition would be established in the Superintendent's Compendium and subject to periodic review.</p>	<p>Same as alternative C.</p>

<b>Periodic Review</b>					
None	Same as alternative A.	Every 5 years NPS would conduct a systematic review of the ORV management measures that are identified in this plan as being subject to Periodic Review. This could result in changes to those management actions in order to improve effectiveness.	Same as alternative A.	Same as alternative C.	Same as alternative C.
<b>Staffing and Material Costs (annual costs based on 2009 dollars)</b>					
Protection: \$1,147,500 Management/Administration: \$428,750 Resource Mgmt: \$508,500 Facilities: \$55,600 Interpretation: \$68,500 Total: \$2,208,850	Protection: \$1,481,500 Management/Administration: \$483,950 Resource Mgmt: \$813,000 Facilities: \$178,600 Interpretation: \$193,500 Total: \$3,150,550	Protection: \$1,706,900 Management/Administration: \$380,100 Resource Mgmt: \$704,000 Facilities: \$198,800 Interpretation: \$193,500 Total: \$3,183,300	Protection: \$1,768,500 Management/Administration: \$360,850 Resource Mgmt: \$649,500 Facilities: \$178,600 Interpretation: \$193,500 Total: \$3,150,950	Protection: \$2,204,300 Management/Administration: \$383,100 Resource Mgmt: \$924,200 Facilities: \$211,400 Interpretation: \$193,500 Total: \$3,916,500	Protection: \$1,956,100 Management/Administration: \$274,150 Resource Mgmt: \$943,950 Facilities: \$194,100 Interpretation: \$263,850 Total: \$3,632,150
<b>Resource Protection Measures</b>					
<b>Breeding Season Measures</b>					
Shorebird prenesting areas and ORV/pedestrian buffers for observed shorebird breeding behavior, sea turtle nests, and seabeach amaranth are established as described in the Interim Strategy FONSI (table 9).	Shorebird prenesting areas and ORV/pedestrian buffers for observed shorebird breeding behavior, sea turtle nests, and seabeach amaranth are established as described in the Interim Strategy FONSI (table 9), as modified by the consent decree.	Breeding Shorebird SMAs would be designated. Shorebird prenesting areas and ORV/pedestrian buffers for observed shorebird breeding behavior, sea turtle nests, and seabeach amaranth would be established as described in table 10.  ML1 measures would be implemented at all locations (including those outside of SMAs), except at Bodie Island Spit, Cape Point, and South Point Ocracoke, where ML2 measures would be implemented.  Designated SMAs would be subject to periodic review.	Same as alternative C, except: • ML1 would be implemented at all locations.	Same as alternative C, except: • ML2 areas at Bodie Island Spit, Cape Point, and South Point Ocracoke would include an ORV pass-through zone, using standard buffer distances as described in table 10.	Prenesting areas and buffers would be established as described in table 10-1. Pedestrian shoreline access below the high tide line would be permitted in front of (i.e., seaward of) prenesting areas until breeding activity is observed, then standard buffers for breeding activity would apply. The NPS retains discretion at all times to enforce more protective closures or take other measures, if considered necessary, consistent with its obligations under the law.
<b>Nonbreeding Season Measures</b>					
As described in the Interim Strategy FONSI: Suitable interior habitats at spits and at Cape Point are closed year-round to all recreational users to provide for resting and foraging for shorebirds. Suitable habitats include ephemeral ponds and moist flats at Cape Point, Hatteras Spit, Ocracoke, and Bodie Island Spit. Actual locations of suitable foraging and resting habitat may change periodically due to natural processes and are determined based on annual habitat assessment and monitoring.	Same as alternative A.	Nonbreeding Shorebird SMAs would be established at the points and spits based on an annual habitat assessment. In addition, year-round VFAs along the ocean shoreline outside of the villages, as identified in table 7, would be managed as Nonbreeding Shorebird SMAs with recreational activity restrictions as described in table 10.  Designated SMAs would be subject to periodic review.	Same as alternative C.	Same as alternative C.	VFAs throughout the Seashore would provide relatively less disturbed foraging, resting, and roosting habitat for migrating and wintering birds. These areas would be managed as described in table 10-1.

<b>Vegetation</b>					
ORV use is generally restricted to minimize impacts.	Same as alternative A.	ORV use would be restricted or prohibited in locations where ORV use is causing unacceptable impacts to vegetation.	Same as alternative C.	Same as alternative C.	Same as alternative C.

**TABLE ES-4. ANALYSIS OF HOW ALTERNATIVES MEET OBJECTIVES**

Objectives	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Management Methodology</b>						
Identify criteria to designate ORV routes and areas.	Meets objective to some degree. No criteria would be developed to designate routes and areas. The ocean and inlet shoreline and existing soundside routes would potentially be open to ORV use 24 hours a day, year-round.	Meets objective to some degree. No criteria would be developed to designate routes and areas. The ocean and inlet shoreline and existing soundside routes would potentially be open to ORV use, year-round.	Meets objective to a large degree. Routes and areas designated based on seasonal resource and visitor use characteristics of various areas in the Seashore.	Meets objective to a large degree. Routes and areas designated based on providing predictability for visitors and simplified management strategies.	Meets objective to a large degree. Routes and areas designated based on providing a wide variety of access opportunities for all users, while still protecting sensitive resources.	Meets objective to a large degree. Routes and areas designated based on providing a variety of access opportunities for all users, while still protecting sensitive resources. This alternative also provides more predictability than alternative E.
Establish ORV management practices and procedures that have the ability to adapt in response to changes in the Seashore’s dynamic physical and biological environment.	Meets objective to a moderate degree. ORV use areas are determined by where resource management closures exist. Flexibility to adapt to changes, but lack of a framework to make these changes efficiently.	Meets objective to some degree. ORV use areas are set through resource management measures under the Consent Decree. Areas are set, but are rigid, and do not have flexibility to adapt as needed to respond to changing environment.	Meets objective to a large degree. Route, areas, and ORV management measures are established that are subject to Periodic Review of both ORV management and species management measures.	Meets objective to some degree. Route, areas, and ORV management measures are established that are subject to Periodic Review and species management measures, but not ORV management measures. The ability to implement safety closures would not be available.	Meets objective to a large degree. Route, areas, and ORV management measures are established that are subject to Periodic Review of both ORV management and species management measures.	Meets objective to a large degree. Route, areas, and ORV management measures are established that are subject to Periodic Review of both ORV management and species management measures.
Establish a civic engagement component for ORV management.	Meets objective to a moderate degree. The Seashore would conduct educational programs during bird and turtle hatching season, which would involve students from public schools, as well as other public involvement activities that engage the public.	Meets objective to a moderate degree. The Seashore would conduct educational programs during bird and turtle hatching season, which would involve students from public schools, as well as other public involvement activities that engage the public.	Meets objective to a large degree as the Seashore would implement more educational programs in local schools, expand the Junior Ranger program, and enlist volunteers for a Sea Turtle Nest Watch Program.	Meets objective to a large degree as the Seashore would implement more educational programs in local schools, expand the Junior Ranger program, and enlist volunteers for a Sea Turtle Nest Watch Program.	Meets objective to a large degree as the Seashore would implement more educational programs in local schools, expand the Junior Ranger program, and enlist volunteers for a Sea Turtle Nest Watch Program.	Meets objective to a large degree as the Seashore would implement more educational programs in local schools, expand the Junior Ranger program, and enlist volunteers for a Sea Turtle Nest Watch Program.
Establish procedures for prompt and efficient public notification of beach access status, including any temporary ORV use restrictions for such things as ramp maintenance, resource and public safety closures, storm events, etc.	Meets objective to some degree. Weekly beach access reports and online news releases provide prompt public notification.	Meets objective to a moderate degree. Weekly beach access reports, online news feeds, and Google Earth maps provide efficient beach access status updates.	Fully meets objective. Weekly beach access reports, online news feeds, and Google Earth maps provide efficient beach access status updates. Implementation of a permit system would provide ORV users with information regarding closed areas.	Fully meets objective. Weekly beach access reports, online news feeds, and Google Earth maps provide efficient beach access status updates. Implementation of a permit system would provide ORV users with information regarding closed areas.	Fully meets objective. Weekly beach access reports, online news feeds, and Google Earth maps provide efficient beach access status updates. Implementation of a permit system would provide ORV users with information regarding closed areas.	Fully meets objective. Weekly beach access reports, online news feeds, and Google Earth maps provide efficient beach access status updates. Implementation of a permit system would provide ORV users with information regarding closed areas.
Build stewardship through public awareness and understanding of NPS resource-management and visitor-use policies and responsibilities as they pertain to the Seashore and ORV management.	Meets objective to some degree. Seashore programs would continue to provide information regarding resource management and aim to build stewardship through public awareness.	Meets objective to some degree. Seashore programs would continue to provide information regarding resource management and aim to build stewardship through public awareness. Public opinion regarding the Consent Decree would detract from these efforts.	Meets objective to a large degree. Seashore programs would continue to provide information regarding resource management and aim to build stewardship through public awareness. Additional programs would be implemented and information provided through the permit system would increase awareness of Seashore resources.	Meets objective to a large degree. Seashore programs would continue to provide information regarding resource management and aim to build stewardship through public awareness. Additional programs would be implemented and information provided through the permit system would increase awareness of Seashore resources.	Meets objective to a large degree. Seashore programs would continue to provide information regarding resource management and aim to build stewardship through public awareness. Additional programs would be implemented and information provided through the permit system would increase awareness of Seashore resources.	Meets objective to a large degree. Seashore programs would continue to provide information regarding resource management and aim to build stewardship through public awareness. Additional programs would be implemented and information provided through the permit system would increase awareness of Seashore resources.

Objectives	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Natural Physical Resources</b>						
Minimize impacts from ORV use to soils and topographic features, for example, dunes, ocean beach, wetlands, tidal flats, and other features.	Meets objective to some degree. ORV use not permitted on dunes, but permitted on the ocean and inlet shoreline and existing soundside routes would potentially be open to ORV use 24 hours a day, year-round. Lack of defined areas likely to lead to increased non-compliance and potential for these resources to be impacted.	Meets objective to a moderate degree. ORV use not permitted on dunes, but permitted on the ocean and inlet shoreline and existing soundside routes would potentially be open to ORV use, year-round. Night-driving restrictions reduce amount of disturbance from beach driving. Implementation of larger buffers and backshore closures would offer protection to resources.	Meets objective to a large degree, as ORV use not permitted on dunes, night-driving restrictions, and carrying capacity limits. However, a large amount of beach open to ORV use could result in impacts to physical resources.	Fully meets objective, as ORV use not permitted on dunes, night-driving restrictions, and beach parking limitations. Least amount of mileage open to ORV use year-round would minimize resource impacts.	Fully meets objectives, as ORV use not permitted on dunes, night-driving restrictions, carrying capacity limits, and soundside driving restrictions.	Meets objective to a large degree, as ORV use not permitted on dunes, night-driving restrictions, and carrying capacity limits. However, a large amount of beach open to ORV use could result in impacts to physical resources
<b>Threatened, Endangered, and Other Protected Species</b>						
Provide protection for threatened, endangered, and other protected species (e.g., state-listed species) and their habitats, and minimize impacts related to ORVs and other uses as required by laws and policies such as the <i>Endangered Species Act</i> , the <i>Migratory Bird Treaty Act</i> , and NPS laws and management policies.	Meets objective to some degree, as temporary resource closures provide protection for sensitive species but buffers would require frequent adjustments to provide adequate protection.	Meets objective to a moderate degree, as increased buffer distances and night-driving restrictions provide increased levels of species protection.	Meets objective to a large degree with increased buffer distances, night-driving restrictions, pet regulations, and SMAs closed to ORV use 7 months per year provide proactive (prior to breeding season) protection.	Fully meets objective with increased buffer distances, night-driving restrictions, pet regulations, and SMAs closed to ORV use year-round providing large areas of resource protection.	Meets objective to a large degree with increased buffer distances, night-driving restrictions, pet regulations, and SMAs closed to ORV use 5.5 months per year provide proactive (prior to breeding season) protection.	Meets objective to a large degree with increased buffer distances, night-driving restrictions, pet regulations, prenesting closures and large, pre-determined buffers for breeding/nesting activity would provide proactive (prior to breeding season) protection.
<b>Vegetation</b>						
Minimize impacts to native plant species related to ORV use.	Meets objective to some degree as driving on dune vegetation is prohibited, but lack of defined ORV areas or backshore closures could result in increased non-compliance and impacts to the resource.	Meets objective to a moderate degree as driving on dune vegetation is prohibited and ocean backshore closures are provided. Sensitive areas with marginal width may be open in the winter that would result in non-compliance problems.	Meets objective to a large degree by adding protective signage at soundside parking areas. Location of ORV corridor at the toe of the dune, with no buffer, may impact vegetation.	Fully meets objective as driving on dune vegetation is prohibited. Year-round SMAs protect large areas, reducing potential impacts to vegetation. ORV corridor would provide a 10 meter buffer from the toe of the dune, further protecting vegetation.	Fully meets objective by closing some soundside access areas and adding protective signage at remaining soundside parking areas. ORV corridor would provide a 10 meter buffer from the toe of the dune, further protecting vegetation.	Meets objective to a large degree by adding protective signage at soundside parking areas. However, there is the potential for damage to vegetation from new soundside access points. Location of ORV corridor at the toe of the dune, with no buffer, may impact vegetation.
<b>Other Wildlife and Wildlife Habitat</b>						
Minimize impacts to wildlife species and their habitats related to ORV use.	Meets objective to some degree, as temporary resource closures provide protection for other wildlife species but buffers are not as large as other alternatives and would not offer large levels of protection.	Meets objective to a moderate degree, as increased buffer distances and night-driving restrictions provide increased levels of species protection, which would include protection to other bird and invertebrate species.	Meets objective to a large degree with increased buffer distances, night-driving restrictions, pet regulations, and SMAs closed to ORV use 7 months per year.	Fully meets objective with increased buffer distances, night-driving restrictions, pet regulations, and SMAs closed to ORV use year-round, which would also offer protection to other bird species and invertebrates.	Meets objective to a large degree with increased buffer distances, night-driving restrictions, pet regulations, and SMAs closed to ORV use 5.5 months per year.	Meets objective to a large degree with increased buffer distances, night-driving restrictions, pet regulations, prenesting closures, and year-round and seasonal VFAs that leave areas of the Seashore less disturbed for wildlife.

Objectives	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Cultural Resources</b>						
Protect cultural resources, such as shipwrecks, archeological sites, and cultural landscapes, from impacts related to ORV use.	Meets objective to some degree as Seashore protections would be put in place for cultural resources, such as shipwrecks, but allowing driving at night and allowing access to large areas of the Seashore would provide for more access to these resources and more possibility for these resources to be disturbed.	Meets objective to a moderate degree as Seashore protection would be in place for cultural resources, such as shipwrecks, and seasonal restrictions on night driving would further limit access to these resources. Large areas of the Seashore would still be accessible by ORV and would provide some level of access to these resources.	Meets objective to a large degree as Seashore protection would be in place for cultural resources, such as shipwrecks, and seasonal restrictions on night driving would further limit access to these resources. Further protection would be provided by the establishment of SMAs that limit access to certain areas of the Seashore during certain times of year and the addition of a permit system that could be revoked for non-compliance, decreasing the probability of drivers taking non-compliant actions.	Meets objective to a large degree as Seashore protection would be in place for cultural resources, such as shipwrecks, and seasonal restrictions on night driving would further limit access to these resources. Further protection would be provided by the establishment of SMAs that limit access to certain areas of the Seashore during certain times of year and the addition of a permit system that could be revoked for non-compliance, decreasing the probability of drivers taking non-compliant actions.	Meets objective to a large degree as Seashore protection would be in place for cultural resources, such as shipwrecks, and seasonal restrictions on night driving would further limit access to these resources. Further protection would be provided by the establishment of SMAs that limit access to certain areas of the Seashore during certain times of year and the addition of a permit system that could be revoked for non-compliance, decreasing the probability of drivers taking non-compliant actions.	Meets objective to a large degree as Seashore protection would be in place for cultural resources, such as shipwrecks, and seasonal restrictions on night driving would further limit access to these resources. Further protection would be provided by the establishment of year-round and seasonal VFAs that limit access to certain areas of the Seashore during certain times of year and the addition of a permit system that could be revoked for non-compliance, decreasing the probability of drivers taking non-compliant actions.
<b>Visitor Use and Experience</b>						
Ensure that ORV operators are informed about the rules and regulations regarding ORV use at the Seashore.	Meets objective to some degree as ORV rules are posted at visitor centers, on ORV ramp bulletin boards, in the park newspaper, and on the website. No permit system would be in place to convey information or provide a mechanism for ensuring regulations are followed.	Meets objective to a moderate degree as ORV rules are posted at visitor centers, on ORV ramp bulletin boards, in the park newspaper, on the website, and within the required night-driving permit.	Fully meets objective as ORV rules are posted at visitor centers, on ORV ramp bulletin boards, in the park newspaper, and on the website. This alternative includes a required education component as part of the ORV permit.	Fully meets objective as ORV rules are posted at visitor centers, on ORV ramp bulletin boards, in the park newspaper, and on the website. This alternative includes a required education component as part of the ORV permit.	Fully meets objective as ORV rules are posted at visitor centers, on ORV ramp bulletin boards, in the park newspaper, and on the website. This alternative includes a required education component as part of the ORV permit.	Fully meets objective as ORV rules are posted at visitor centers, on ORV ramp bulletin boards, in the park newspaper, and on the website. This alternative includes a required education component as part of the ORV permit.
Manage ORV use to allow for a variety of visitor use experiences.	Meets objective to some degree as ORV and VFAs are not officially designated. VFAs occur through seasonal and safety closures throughout the Seashore, but no defined use areas exist to provide for a variety of visitor use experiences.	Meets objective to some degree as ORV and VFAs are not officially designated. VFAs occur through seasonal and safety closures throughout the Seashore, but no defined use areas exist to provide for a variety of visitor use experiences.	Meets objective to a moderate degree as more defined areas for ORV and vehicle-free recreational opportunities are provided. New interdunal road access would be provided, offering additional options to ORV users. Some separation of uses and unique opportunities are provided for various user groups.	Meets objective to a moderate degree as more defined areas for ORV and vehicle-free recreational opportunities are provided. New interdunal road access would be provided, offering additional options to ORV users. Some separation of uses and unique opportunities are provided for various user groups, but large areas would be closed to all visitors for most of the year, and would not be available to provide for the visitor experience.	Meets objective to a large degree as more defined areas for ORV and vehicle-free recreational opportunities are provided. New interdunal road access would be provided, offering additional options to ORV users. Additional user opportunities would be provided including the addition of a park-and-stay options, as well as self-contained vehicle camping. The addition of pedestrian routes, additional parking on the soundside, as well as the potential for water taxi access would all contribute to offering a variety of visitor experiences.	Meets objective to a large degree as more defined areas for ORV and vehicle-free recreational opportunities are provided. New interdunal road access would be provided, offering additional options to ORV users. Additional visitor experiences would be provided through pedestrian routes, extra trails, and new parking. Providing some areas of the Seashore that are vehicle-free year-round or seasonally would provide for a greater variety of visitor experiences.

Objectives	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
Minimize conflicts between ORV use and other visitor uses.	Meets objective to some degree as no designated areas for uses are established, which could result in real or perceived conflicts between ORV uses and other visitor uses.	Meets objective to some degree as no designated areas for uses are established, which could result in real or perceived conflicts between ORV uses and other visitor uses.	Meets objective to a large degree as designation of ORV and VFAs would help minimize conflicts. Implementation of a permit system would provide additional education and the ability to revoke permits would likely increase compliance with ORV use regulations and further reduce conflicts. Seasonal night-driving restrictions would also reduce potential visitor use conflicts.	Meets objective to a large degree as designation of ORV and VFAs would help minimize conflicts. Implementation of a permit system would provide additional education and the ability to revoke permits would likely increase compliance with ORV use regulations and further reduce conflicts. Seasonal night-driving restrictions would also reduce potential visitor use conflicts.	Meets objective to a large degree as designation of ORV and VFAs would help minimize conflicts. Implementation of a permit system would provide additional education and the ability to revoke permits would likely increase compliance with ORV use regulations and further reduce conflicts. Seasonal night-driving restrictions would also reduce potential visitor use conflicts.	Meets objective to a large degree as designation of ORV and VFAs would help minimize conflicts. Implementation of a permit system would provide additional education and the ability to revoke permits would likely increase compliance with ORV use regulations and further reduce conflicts. Seasonal night-driving restrictions would also reduce potential visitor use conflicts.
<b>Visitor Safety</b>						
Ensure that ORV management promotes the safety of all visitors.	Meets objective to a moderate degree as ORV safety closures would be provided, as well as right-of-way and unsafe operation regulations contained in the CFR.	Meets objective to a large degree as ORV safety closures would be provided, as well as right-of-way and unsafe operation regulations contained in the CFR. Increased signage, lower speed limits, and increased public awareness would contribute to visitor safety.	Fully meets objective as ORV safety closures would be provided. Reduced speed limits would also apply in all areas. Village beaches would be closed to ORV use during the summer. Permit requirement would provide further information for increasing visitor safety.	Fully meets objective. Although ORV safety closures would not be provided, areas where these occur would be closed year-round as SMAs. Village beaches would be closed to ORVs year-round. Reduced speed limits would also apply in all areas.	Fully meets objective as ORV safety closures would be provided. Reduced speed limits would also apply in all areas. Beach width requirements would limit some ORV use in narrow beach areas and village beaches would be closed to ORV use during the summer.	Fully meets objective. Speed limits, village beach closures, and safety closures would be provided. Also, additional pedestrian safety and right-of-way requirements would provide increased protection.
<b>Seashore Operations</b>						
Identify operational needs and costs to fully implement an ORV management plan.	Meets objective to a large degree as implementation costs have been identified, but carries a degree of uncertainty.	Meets objective to a large degree as implementation costs have been identified, but carries a degree of uncertainty.	Meets objective to a large degree as implementation costs have been identified, but carries a degree of uncertainty.	Meets objective to a large degree as implementation costs have been identified, but carries a degree of uncertainty.	Meets objective to a large degree as implementation costs have been identified, but carries a degree of uncertainty.	Meets objective to a large degree as implementation costs have been identified, but carries a degree of uncertainty.
Identify potential sources of funding necessary to implement an ORV management plan.	Meets objective to a moderate degree. Funding expected under annual budget, but no additional funding source provided.	Meets objective to a moderate degree. Funding expected under annual budget, but no additional funding source provided.	Meets objective to a large degree. Funding expected under annual budget, additional funding would occur by from permit fees utilizing cost recovery.	Meets objective to a large degree. Funding expected under annual budget, additional funding would occur by from permit fees utilizing cost recovery.	Meets objective to a large degree. Funding expected under annual budget, additional funding would occur by from permit fees utilizing cost recovery.	Meets objective to a large degree. Funding expected under annual budget, additional funding would occur by from permit fees utilizing cost recovery.
Provide consistent guidelines, according to site conditions, for ORV routes, ramps, and signage.	Meets objective to some degree. Guidelines are not set and conditions would not be predictable.	Meets objective to a moderate degree. Increased signage would be consistent, but no consistent guidelines for routes and ramps would exist.	Meets objective to a large degree. Guidelines for ramp establishment and maintenance, signage, and routes would be established.	Meets objective to a large degree. Guidelines for ramp establishment and maintenance, signage, and routes would be established.	Meets objective to a large degree. Guidelines for ramp establishment and maintenance, signage, and routes would be established.	Meets objective to a large degree. Guidelines for ramp establishment and maintenance, signage, and routes would be established.

Note: Objectives are measured as fully meets objective, largely meets objective, moderately meets objective, or meets objective to some degree.

TABLE ES-5. ENVIRONMENTAL IMPACT SUMMARY BY ALTERNATIVE

Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Wetlands and Floodplains</b>						
<b>Wetlands</b>	<b>Impacts of the Alternative on Marine Intertidal Wetlands:</b> Under all alternatives, there would be short term, negligible adverse impacts to marine intertidal wetlands due to continued ORV use in these areas					
	<p><b>Impacts of the Alternative:</b> Under alternative A, there would be long-term minor adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the sound side and along interior ORV routes.</p> <p>There would be no construction (or related impacts) under the no-action alternatives.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wetlands would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Under alternative B, there would be long-term minor adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the sound side and along interior ORV routes.</p> <p>There would be no construction (or related impacts) under the no-action alternatives.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wetlands would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Under alternative C, there would be long-term negligible adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the sound side and along interior ORV routes. Impacts to soundside wetlands would remain at a negligible level due to the protection provided by the installation of signage.</p> <p>Construction activities would avoid wetland areas, resulting in indirect, long-term negligible adverse impacts to wetlands.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wetlands would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Under alternative D, there would be long-term negligible to minor adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the sound side, which would not be protected with signage. Impacts to vegetated wetlands along interior ORV routes would continue.</p> <p>Construction activities would avoid wetland areas, resulting in indirect long-term negligible adverse impacts to wetlands.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wetlands would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Under alternative E, there would be long-term negligible adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the sound side and along interior ORV routes. Impacts to soundside wetlands would remain at a negligible level due to the protection provided by signage and closures of soundside access points.</p> <p>Construction activities would avoid wetland areas, resulting in indirect long-term negligible adverse impacts to wetlands.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wetlands would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Under alternative F, there would be long-term negligible adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the sound side and along interior ORV routes. Impacts to soundside wetlands would remain at a negligible level due to the protection provided by the installation of signage.</p> <p>Construction activities would avoid wetland areas, resulting in indirect long-term negligible adverse impacts to wetlands.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wetlands would be long-term minor to moderate adverse.</p>
<b>Floodplains</b>	<p><b>Impacts of the Alternative:</b> There would be no construction under alternative A. As a result, there would be no impacts to the functions or values of floodplains.</p> <p><b>Cumulative Impacts:</b> No cumulative impacts would occur.</p>	<p><b>Impacts of the Alternative:</b> There would be no construction under alternative B. As a result, there would be no impacts to the functions or values of floodplains.</p> <p><b>Cumulative Impacts:</b> No cumulative impacts would occur.</p>	<p><b>Impacts of the Alternative:</b> Under alternative C, there would be long-term minor adverse impacts to floodplains due to the construction or expansion of seven parking areas in the floodplain.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to floodplains would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Under alternative D there would be long-term negligible adverse impacts to floodplains due to the location of four ORV access ramps in the 100-year floodplain.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to floodplains would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Under alternative E, there would be long-term minor adverse impacts to floodplains due to the construction or expansion of 14 parking areas in the floodplain.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to floodplains would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Under alternative F, there would be long-term minor adverse impacts to floodplains due to the construction or expansion of 12 surfaced and 2 unsurfaced parking areas in the floodplain.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to floodplains would be long-term minor to moderate adverse.</p>

Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Federally Listed Threatened or Endangered Species</b>						
<p><b>Piping Plover</b></p>	<p><b>Impacts of the Alternative:</b> Overall, impacts to piping plover from resource management activities (primarily as a result of surveys and field activities) would be long-term minor to moderate adverse. Although the management of the species would provide a certain level of benefit, the manner in which buffers would be established, along with the need to adjust buffers frequently would have an adverse impact on the species.</p> <p>Overall, impacts to piping plover from ORV and other recreational use would be long-term moderate to major adverse as much of the Seashore would be open to recreational use, with an increased potential that piping plover could be impacted due to disturbance from ORV use and other recreational activities. Lack of a permit system for education and law enforcement, no night-driving restrictions, and lack of compliance with pet leash requirements would contribute substantially to these adverse impacts.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to piping plover would be long-term moderate to major adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, impacts under alternative B from resource management activities (primarily resulting from the effects of surveying and field activities) would be long-term minor to moderate beneficial. Buffers for piping plover would be larger and provide more protection compared to buffers under alternative A. Minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of prenesting closures early in the breeding season, monitoring activities, education and outreach efforts, and establishment of prescribed buffers would provide long-term minor to moderate beneficial impacts to the species.</p> <p>Overall, impacts to piping plover from ORV and other recreational use would be long-term moderate adverse. While some buffers would be increased in an attempt to separate recreational uses from piping plover, access to these buffers would be provided at all Seashore beaches and could result in intentional or un-intentional non-compliance (i.e., when signs are washed out), which would impact the species. Adverse impacts would also occur due to limited prenesting protection outside of the points and spits, and the potential for protective buffers to be reduced during critical life stages of plover chicks.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to piping plover would be long-term moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall impacts under alternative C from resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term moderate beneficial. As with alternative B, minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of SMAs early in the breeding season, monitoring activities, and establishment of prescribed buffers would provide long-term moderate beneficial impacts to the species.</p> <p>Overall, impacts to piping plover from ORV and other recreational use would be long-term minor adverse. The establishment of the SMAs which proactively reduce or preclude recreational use early in the breeding season, ORV permit requirements, seasonal night-driving restrictions, and pet and other recreational activity restrictions would all provide benefits in terms of species protection. As there would still be some opportunity for recreational use to come in contact with and impact piping plovers, and the fact that alternative C would still include some level of pedestrian access to three SMAs during a portion of the breeding season, impacts to piping plover would be long-term minor adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to piping plover would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall impacts to piping plover from resources management activities (primarily resulting from the effects of surveying and field activities) under alternative D would be long-term moderate to major beneficial. As with all species management activities, minor adverse impacts would occur from human presence during monitoring, but on the whole the implementation of SMAs that prohibit ORV use year-round and only allow pedestrian access outside of the breeding season, establishment of prenesting closures early in the breeding season, monitoring activities, and establishment of prescribed buffers would provide long-term moderate to major beneficial impacts to the species.</p> <p>Overall impacts from ORV and other recreational use would be long-term minor adverse. The establishment of SMAs that are closed to ORVs year-round and managed under ML1 procedures during the breeding season would proactively preclude recreational use early in the breeding season from large areas of the Seashore, which would reduce the potential for disturbance to plovers during critical life stages. This protection, combined with ORV permit requirements, seasonal night-driving restriction, and pet and other recreational activities restrictions would all provide benefits in terms of species protection. As there would still be some opportunity for recreational use to come in contact with and impact the species, impacts would be long-term minor adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to piping plover would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall impacts under alternative E from resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term moderate beneficial. As with all species management activities, minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of SMAs early in the breeding season, monitoring activities, and establishment of prescribed buffers would provide long-term moderate beneficial impacts to the species.</p> <p>Overall impacts from ORV and other recreational use would be long-term minor to moderate adverse. The establishment of the SMAs which proactively reduce or preclude recreational use early in the breeding season, ORV permit requirements, and pet and other recreational activity restrictions would all provide benefits in terms of species protection. Although there would be benefits from seasonal night-driving restrictions, they would not be as great as other action alternatives because driving after dark (until 10:00 p.m.) would still be occurring, even during seasonal restrictions. The potential for adverse impacts would exist from the park-and-stay option under this alternative. As there would still be some opportunity for recreational use to come in contact with and impact the species, impacts would be long-term minor to moderate adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to piping plover would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall impacts under alternative F from resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term moderate and beneficial for piping plovers. As with all species management activities, minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of prenesting closures, monitoring activities, and establishment of prescribed buffers would provide long-term moderate beneficial impacts to the species. Long-term moderate benefits to nonbreeding populations would be greater under alternative F than under alternatives C or E because of the addition of the year-round VFAs.</p> <p>Overall impacts under alternative F from ORV and other recreational use would be long-term minor to moderate adverse. The establishment of prenesting closures, year-round and seasonal VFAs, ORV permit requirements, and pet and other recreational activity restrictions would all provide benefits in terms of species protection. As alternative F would provide for more flexible access to various areas of the Seashore, the potential for disturbance to piping plover is increased over alternatives C and D, resulting in long-term minor to moderate adverse impacts.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to piping plover would be long-term minor to moderate adverse.</p>

Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<p><b>Sea Turtles</b></p>	<p><b>Impacts of the Alternative:</b> Overall, resources management activities under alternative A would have long-term moderate benefits due to the protection provided to sea turtles.  Overall, ORV and other recreational use under alternative A would result in long-term major adverse impacts to sea turtles due to the amount of Seashore available for ORV use and the lack of night-driving restrictions.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to sea turtles would be long-term moderate to major adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, resource management activities under alternative B would have long-term moderate benefits due to the protection provided to sea turtles.  Although additional restrictions and regulations would help lessen some of the impacts from ORV use and other recreational activities, overall, the impacts would be long-term moderate adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to sea turtles would be long-term moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, resource management activities under alternative C would have long-term moderate to major beneficial impacts due to the added protection provided to sea turtles.  Restrictions placed on nonessential, recreational ORV use under alternative C would provide substantial long-term benefits to sea turtles, including seasonal night-driving restrictions that close the beach before dark (7:00 p.m.), some adverse impacts would still occur in areas where their use is allowed. Therefore, overall, ORV and other recreational use would have long-term minor adverse impacts.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to sea turtles would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, similar to alternative C, management activities under alternative D would result in long-term moderate to major beneficial impacts.  While restrictions placed on ORV use under alternative D would provide long-term moderate to major beneficial impacts, similar to alternative C, there would still be some level of adverse impact to sea turtles in areas where ORV use and beach fires are allowed; therefore, overall impacts from ORV and other recreational use would be long-term minor adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to sea turtles would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> Management activities would provide long-term moderate to major beneficial impacts to sea turtles.  While additional restrictions and regulations would help lessen some of the impacts from ORVs and other recreational activities, overall, the impacts would be long-term moderate adverse from allowing night driving until 10:00 p.m., and due to increased recreational access throughout the Seashore during the turtle nesting season, including a park-and-stay option for ORVs at selected points and spits.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to sea turtles would be long-term moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, resource management activities would provide long-term moderate to major beneficial impacts to sea turtles.  While additional restrictions, such as prohibiting night driving from 9:00 p.m. to 7:00 a.m and regulations would help lessen some of the impacts from ORV and other recreational use, overall, the impacts would be long-term minor to moderate adverse, due to not prohibiting night driving prior to 9:00 p.m. and the earlier re-opening of prenesting areas (after shorebird breeding activity has concluded), resulting in increased recreational access throughout the Seashore during the sea turtle nesting season.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to sea turtles would be long-term minor to moderate adverse.</p>
<p><b>Seabeach Amaranth</b></p>	<p><b>Impacts of the Alternative:</b> Overall, because of the protection of seabeach amaranth habitat and plants under alternative A, resources management actions would have long-term minor to moderate beneficial impacts, if plants are detected.  Overall, ORV and other recreational use under alternative A would have long-term moderate adverse impacts as plants may go undetected and therefore unprotected from this use.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to seabeach amaranth would be long-term moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, because of the protection of seabeach amaranth habitat and plants under alternative B, resources management actions would have long-term minor to moderate beneficial impacts, if plants are detected.  Overall, ORV and other recreational use would result in long-term moderate adverse impacts. Slightly more protection would be provided for the species when compared to alternative A, due to shorebird breeding closures being larger and lasting longer.</p> <p><b>Cumulative Impacts:</b> Cumulative to seabeach amaranth would be long-term moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, because of the protection of seabeach amaranth habitat and plants under alternative C, resources management actions would have long-term moderate beneficial impacts to seabeach amaranth as the establishment of SMAs and increased protection for the species would occur compared to alternatives A and B.  Overall, ORV and other recreational use would result in long-term minor to moderate adverse impacts. Because of the establishment of SMAs and protection of approximately 40 miles of beach, the adverse impacts under alternative C would likely be long-term minor to moderate adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to seabeach amaranth would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, because of the increased level of protection of seabeach amaranth habitat and plants under alternative D, when compared to other alternatives, resources management actions would have long-term moderate to major beneficial impacts.  Overall ORV and other recreational use would result in long-term minor adverse impacts. Because the establishment of SMAs closed to ORVs year-round would protect approximately 40 miles of beach, the adverse impacts under alternative D would be greatly reduced compared to the other alternatives and result in long-term minor adverse impacts.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to seabeach amaranth would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, because of the protection of seabeach amaranth habitat and plants under alternative E, resources management actions would have long-term minor to moderate beneficial impacts as ORV access to more areas would be allowed during the germination period, than under action alternatives C and D.  Overall, ORV and other recreational use would have long-term minor to moderate adverse impacts to seabeach amaranth due to the increased level of recreational access allowed when compared to the other action alternatives.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to seabeach amaranth would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, because of the protection of seabeach amaranth habitat and plants under alternative F, resources management actions would have long-term minor to moderate beneficial impacts as ORV access to more areas would be allowed during the germination period, than under action alternatives C and D.  Overall, ORV and other recreational use would be similar to those under alternative E and result in long-term minor to moderate adverse impacts to seabeach amaranth.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to seabeach amaranth would be long-term minor to moderate adverse.</p>

<b>State-Listed and Special Status Species</b>						
<b>American Oystercatcher</b>	<b>Impacts of the Alternative:</b> Impacts would be long-term minor to moderate adverse as surveying and lack of specific prenesting closures for this species may miss early nesters. Piping plover prenesting closures, which could be utilized by this species as well, would not protect a number of American oystercatcher nest sites used in recent years. Also, buffer distances based on bird behavior may not provide adequate protection for the species.	<b>Impacts of the Alternative:</b> Establishment of piping plover prenesting closures earlier in the season that could be used by oystercatchers and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts related to human disturbance during field activities, resources management activities on the whole would provide information and result in actions that would be beneficial to the species.	<b>Impacts of the Alternative:</b> Implementation of 10 SMAs that are closed to ORVs during the breeding season would provide a proactive resource closure early in the breeding season. Establishment of prenesting closures earlier in the season and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts related to human disturbance during field activities, on the whole, resources management activities would provide information that would enable the implementation of adaptive management initiatives and contribute to better management. These activities would result in long-term beneficial impacts to the American oystercatcher, greater than those provided under alternative B.	<b>Impacts of the Alternative:</b> Establishment of 10 SMAs that are closed to ORVs year-round and all managed under ML1 procedures during the breeding season would provide long-term benefits to breeding and wintering American oystercatchers, greater than those under alternative C. Additional benefits would be provided from surveying and closures outside of these established SMAs, as well as from the education and outreach provided. These surveying and field activities would provide information that would enable the implementation of adaptive management initiatives and contribute to better management. These activities would result in long-term beneficial impacts to this species, greater than those provided under alternative B.	<b>Impacts of the Alternative:</b> Implementation of 10 SMAs, 7 of which are closed to ORVs during the breeding season, would provide a proactive resource closure early in the breeding season. Establishment of prenesting closures earlier in the season and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts from human disturbance during field activities, resources management activities on the whole would provide information that would enable the implementation of adaptive management initiatives and contribute to better management. These activities would result in long-term beneficial impacts to this species, greater than those provided under alternative B.	<b>Impacts of the Alternative:</b> Implementation of prenesting closures would provide a proactive resource closure early in the breeding season. Seasonal and year-round VFAs that total 39 miles of Seashore would provide additional areas with less disturbance for shorebirds. Establishment of prenesting closures earlier in the season and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts related to human disturbance during field activities, resources management activities on the whole would provide information that would enable the implementation of adaptive management initiatives and contribute to better management. These activities would result in long-term beneficial impacts to the species, greater than those provided under alternative B.

Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<p><b>American Oystercatcher (continued)</b></p>	<p>Impacts would be long-term moderate to major adverse as buffers that adjust frequently based on bird behavior are more subject to non-compliance. The lack of designated VFAs, a permitting system, carrying capacity, or seasonal night-driving restrictions, and allowing pets at the Seashore during breeding season would contribute to these adverse impacts.</p>	<p>Establishment of prenesting closures for piping plover earlier in the season, implementation of larger, more immediate buffers, longer lasting closures for American oystercatchers once breeding behavior occurs, and night-driving restrictions would benefit the American oystercatcher. However, recreational use, with no carrying capacity, would still occur in the vicinity of this species and the established buffers may not be large enough to afford adequate protection. Because the birds would not be under constant observation, disturbance may go undetected and implementation of adequate buffers may be delayed in some nesting locations. Compliance with closures may not be absolute, resulting in minor to moderate adverse impacts if non-compliance occurs. Further adverse impacts would result from allowing pets in the Seashore during breeding season, resulting in the possibility of non-compliance with these regulations. Because of these factors, impacts to American oystercatchers from ORV use and other recreational activities would be long term moderate adverse.</p>	<p>Implementation of a permit system with an educational component, larger buffer sizes, seasonal night-driving restrictions, establishment of breeding and nonbreeding SMAs, and not allowing pets in SMAs would benefit the American oystercatcher. SMAs would provide a proactive method of limiting recreational uses early in the breeding season, and limit the potential for impacts to state-listed/special status species. However, alternative C does manage three SMAs under ML2 procedures, which provide for some level of pedestrian access into these areas, and introduces the potential for impacts to the species. Although there would be some protection measures in place, ORV and other recreational use could still have impacts to the species, resulting in long-term minor to moderate adverse impacts to American oystercatchers.</p>	<p>Providing large SMAs that are closed year-round to ORVs and closed to pedestrians during the breeding season would provide large undisturbed areas for both breeding and nonbreeding oystercatchers. Further benefits would be provided by seasonal night-driving restrictions, the establishment of a permit system with an educational component, and prohibition of pets in SMAs year-round. With these measures in place, impacts to American oystercatchers from ORV and other recreational use would be long-term minor adverse, as the chance of disturbance still exists, but would be lower than that under the other alternatives evaluated.</p>	<p>Implementation of a permit system with an educational component, larger buffer sizes, seasonal night-driving restrictions, restrictions on pets in SMAs, and establishment of breeding and nonbreeding SMAs would benefit the American oystercatcher. SMAs would provide a proactive method of limiting recreational uses early in the breeding season, and limit the potential for impacts to state-listed/special status species. However, alternative E does allow an ORV access corridor at three SMAs managed under ML2 procedures during the breeding season (more than the other action alternatives), which provide for some level of pedestrian or ORV access into these areas, which introduces the potential for impacts to the species. Although there would be some protection measures in place, recreational use could still result in long-term minor to moderate adverse impacts to American oystercatchers.</p>	<p>Implementation of a permit system with an educational component, prenesting closures, seasonal night-driving restrictions, allowing pets under the regulations of 36 CFR 2.15 with the additional prohibition of pets in resource closures and in pedestrian shoreline access areas in front of (i.e., seaward of) bird prenesting areas and establishment of seasonal and year-round VFAs that total 39 miles of Seashore would benefit the American oystercatcher. Prenesting closures would provide a proactive method of limiting recreational uses early in the breeding season, and limit the potential for impacts to state-listed/special status species, with additional areas that are relatively less disturbed provided by prenesting closures. However, alternative F does manage all areas of the Seashore to allow for ORV and/or pedestrian access, which introduces the potential for impacts to the species. As there would be some protection measures in place, but recreational use could still have impacts to the species, impacts to American oystercatchers would be long-term minor to moderate adverse.</p>

Wildlife and Wildlife Habitat - Invertebrates	<b>Impacts of the Alternative Common to All:</b> The use of vehicles to conduct resources management activities would result in long-term negligible adverse impacts to invertebrates due to the potential for mortality of individual invertebrate species.					
	<p><b>Impacts of the Alternative:</b> Recreational ORV use would result in long-term minor to moderate adverse impacts to invertebrate species primarily due to mortality arising from unlimited night driving in the intertidal and wrack areas.</p> <p>There would be no construction and therefore no construction-related to disturbance to invertebrates under the no-action alternatives.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wildlife and wildlife habitat (invertebrates) would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Recreational ORV use would result in long-term minor adverse impacts to invertebrate species resulting from the continued use of ORVs in invertebrate habitat. Impacts would be reduced when compared to alternative A due to limitations on ORV use at night and within the larger resources management closures under alternative B.</p> <p>There would be no construction and therefore no construction-related to disturbance to invertebrates under the no-action alternatives.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wildlife and wildlife habitat (invertebrates) would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Recreational ORV use would result in long-term negligible to minor adverse impacts to invertebrate species resulting from the continued use of ORVs in invertebrate habitat. Impacts would be reduced due to longer seasonal restrictions on vehicle use under alternative C.</p> <p>Short term negligible adverse impacts to invertebrates would occur due to temporary displacement during construction activities.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wildlife and wildlife habitat (invertebrates) would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> Recreational ORV use would result in long-term negligible adverse impacts to invertebrate species resulting from the continued use of ORVs in invertebrate habitat. Impacts to invertebrates would be reduced under this alternative due to the amount of beach closed to recreational use.</p> <p>Short term negligible adverse impacts to invertebrates would occur due to temporary displacement during construction activities.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wildlife and wildlife habitat (invertebrates) would be long-term negligible to minor adverse.</p>	<p><b>Impacts of the Alternative:</b> Recreational ORV use would result in long-term minor adverse impacts to invertebrate species resulting from the continued use of ORVs in invertebrate habitat. Adverse impacts would be greater than those under alternatives C or D due to the increased level of recreational access provided under alternative E.</p> <p>Short term negligible adverse impacts to invertebrates would occur due to temporary displacement during construction activities.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wildlife and wildlife habitat (invertebrates) would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> Recreational ORV use would result in long-term minor adverse impacts to invertebrate species resulting from the continued use of ORVs in invertebrate habitat.</p> <p>Short term negligible adverse impacts to invertebrates would occur due to temporary displacement during construction activities.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wildlife and wildlife habitat (invertebrates) would be long-term minor adverse.</p>

Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Soundscapes</b>	<p><b>Impacts of the Alternative:</b> Overall, minor to moderate impacts, depending upon vehicle speed, would occur along the beaches where most routes are established for ORV driving. While impacts over the majority of the Seashore beaches would be long-term adverse due to greater numbers of designated year-round ORV routes, impacts would be short-term adverse in the areas in front of village beaches, which are only opened seasonally to ORV use. Short-term adverse impacts would also result during other closure periods along any ORV route for resource protection, safety or administrative purposes. During closures, the potential for increased vehicle concentrations along remaining open ORV routes would increase the frequency of occurrence of single ORV pass-by events. Impacts would remain minor to moderate adverse, depending on vehicle speed, but vehicle noise may dominate the natural soundscape more frequently. In general, as ORV use would continue intermittently over the life of the management plan, vehicle noise would be a recurring, long-term minor to moderate adverse impact in all areas of the Seashore beaches open to ORV driving. Additionally, as closure periods, which have the potential to provide short-term benefits, would be implemented throughout the life of the management plan, long-term benefits would arise. As noise from ORV use would add at least 3 decibels (A-weighted scale) (dBA) to the natural ambient sound levels within the Seashore, wildlife would also experience adverse impacts.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to soundscapes would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> As described under alternative A, impacts to the natural soundscape within the Seashore would be minor to moderate, depending upon vehicle speed. Due to the slower speed limits proposed during the peak season when more visitors would be using beach areas, the potential for a greater reduction in visitor awareness would occur under this alternative as compared to alternative A. On beaches where ORV routes are open year-round, including the additional year-round route established under alternative B, impacts would be long-term and adverse, but would potentially become short-term adverse during closure periods. In locations where ORV routes are specifically designated as “seasonal,” impacts would be short-term adverse. As with alternative A, closures of any kind present the potential for increased concentrations of vehicles in areas where ORV routes remain open. In such areas, the potential for vehicle noise to more frequently dominate the sound energy would arise. Aside from the short-term benefits that would occur in areas undergoing closure periods of any kind, additional short-term benefits may occur under alternative B as a result of regulations imposed to seasonally eliminate night driving. Impacts to wildlife would be similar to those under alternative A.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to soundscapes would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> As described under alternative B, impacts to the natural soundscape resulting from a 15 mph speed limit would be minor adverse. However, the potential for wildlife and visitor use impacts, as well as the extent of such impacts, may be reduced due to seasonal restrictions and designated VFAs. Like under alternatives A and B, impacts would be long-term adverse for year-round ORV areas, potentially becoming short-term subject to temporary resource closures. As seasonal closures would limit ORV activity to less than a year, short-term adverse impacts would result. Closures of any kind, depending on the closure length, would also provide short-term benefits by providing noise-free periods. Under alternative C there would be areas of negligible impacts due to designated VFAs and greater opportunities for natural sounds to prevail due to longer seasonal closure periods as compared to alternatives A and B. Conversely, fewer open ORV areas and longer seasonal closure periods also present the potential for greater concentrations of ORVs in areas with open ORV routes, thereby increasing the frequency of vehicle noise in such areas. Construction activities would be localized and of short duration and would be minor adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to soundscapes would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> As described under alternative A, impacts to the natural soundscape resulting from a 15 mph speed limit would be minor adverse. However, the potential for impacts to wildlife and visitor use from ORV noise would be the least under this alternative, as compared to the no-action and all action alternatives due to larger areas of designated vehicle-free use. During resource closures, short-term benefits would occur due to the lack of ORV noise and would also be long-term benefits since closures would recur throughout the life of the management plan. The key difference between this alternative and all other alternatives is that alternative D has the greatest extent of long-term negligible adverse impacts resulting from the number of year-round vehicle-free designations. Alternative D also has the greatest extent of long-term benefits to the natural soundscape, visitors and wildlife due to these VFAs. However, this alternative would also present the greatest potential for increased ORV pass-by events that dominate the sound energy in designated ORV areas due to the fewer number of open ORV areas in which vehicles may drive. Like under alternative C, construction related noise impacts from ramp improvements and the construction of a new ramp would be minor adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to soundscapes would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> As described under alternative A, impacts to the natural soundscape on the beaches resulting from a 15 mph speed limit would be minor adverse. However, like under alternative C, the potential for wildlife and visitor use impacts, as well as the extent of such impacts, may be reduced due to seasonal restrictions and designated VFAs. On the other hand, pass-through zones and earlier openings along seasonal routes under this alternative would potentially provide fewer “noise-free” periods for visitors and wildlife. Vehicle diversions to other open routes may not be as frequent under this alternative as under alternative C or D given that some seasonal routes are open longer than others, ORV pass-through zones would be established in certain areas, and water taxi service would be available as an alternative option to driving. Although under this alternative, more ramps would be constructed, as compared to alternatives C and D, construction-related impacts would remain minor adverse due to the localized nature and short duration of the activities.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts under alternative E would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> As described under alternative A, impacts to the natural soundscape on the beaches resulting from a 15 mph speed limit would be minor adverse. Like under alternatives C and E, the potential for wildlife and visitor use impacts from ORV noise may be reduced due to seasonal closures and designated VFAs. “Noise-free” periods would be greater than alternatives C and E. Vehicle diversions to other open routes may not be as frequent under this alternative as under the other action alternatives given that some seasonal routes are open longer than others. Although under this alternative, more ramps would be constructed, as compared to alternatives C and D, construction-related impacts would remain minor adverse due to the localized nature and short duration of the activities.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts under alternative F would be long-term minor adverse.</p>

Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<p><b>Visitor Use and Experience</b></p>	<p><b>Impacts of the Alternative:</b>                      Those looking for an experience at the Seashore that includes ORV use would have long-term negligible to minor adverse impacts as some areas would be closed for resource protection, but alternative A would provide the most ORV access of any alternative. Should there be extensive resource closures in a given year, the potential for long-term moderate impacts exists. Those looking for a vehicle-free experience at the Seashore would experience long-term moderate adverse impacts as alternative A does not provide for a specific separation of uses or designation of VFAs. Since night driving would be permitted under alternative A, there would be short-term minor adverse impacts to night skies.</p> <p><b>Cumulative Impacts:</b>                      Cumulative impacts would be long-term negligible to minor adverse for ORV users and long-term, moderate, and adverse for visitors who desire a vehicle-free beach experience.</p>	<p><b>Impacts of the Alternative:</b>                      Those looking for an experience at the Seashore that includes ORV use would have long-term moderate to major adverse impacts as one or more spit or point would be closed for an extended period of time during the breeding season. During the remainder of the year, there would be negligible to minor adverse impacts to ORV users as limited areas would be closed for resource protection. Those looking for a vehicle-free experience at the Seashore would experience long-term moderate adverse impacts as alternative B does not provide for a specific separation of uses outside of seasonal ORV closures of village beaches and no VFAs would be designated. Since night driving would be seasonally restricted under alternative B, there would be long-term negligible to minor adverse impacts to night skies, with long-term beneficial impacts during times of seasonal night-driving restrictions.</p> <p><b>Cumulative Impacts:</b>                      Cumulative impacts would be long-term moderate to major adverse for ORV users, and long-term moderate adverse for visitors who desire a vehicle-free beach experience.</p>	<p><b>Impacts of the Alternative:</b>                      Those looking for an experience at the Seashore that includes ORV use would have long-term moderate to major adverse impacts as the designation of VFAs and the establishment of the SMAs would seasonally preclude ORV use from some areas of the Seashore that are popular ORV use areas. While three areas managed under ML2 procedures would have pedestrian access corridors, no ORV corridors would be provided in the SMAs, resulting in greater impacts to ORV users. Those looking for a vehicle-free experience at the Seashore would experience long-term benefits as alternative C provides for pedestrian corridors in three SMAs under ML2 procedures, as well as providing additional VFAs. Since night driving would be seasonally restricted under alternative C, there would be long-term negligible to minor adverse impacts to night skies, with long-term beneficial impacts during times of seasonal night-driving restrictions.</p> <p><b>Cumulative Impacts:</b>                      Cumulative impacts would be long-term moderate to major adverse to ORV users, and long-term beneficial for visitors who desire a vehicle-free beach experience.</p>	<p><b>Impacts of the Alternative:</b>                      Those looking for an experience at the Seashore that includes ORV use would have long-term major adverse impacts as all SMAs and village beaches would be designated as VFAs year-round, which would prohibit the use of ORV in many popular visitor use areas. Those looking for a vehicle-free experience at the Seashore would experience long-term benefits as alternative D provides for many designated VFAs throughout the Seashore, although pedestrian access would be prohibited in the SMAs during the breeding season. Since night driving would be seasonally restricted under alternative D, there would be long-term negligible to minor adverse impacts to night skies, with long-term beneficial impacts during times of seasonal night-driving restrictions.</p> <p><b>Cumulative Impacts:</b>                      Cumulative impacts would be long-term major and adverse to ORV users, and long-term beneficial for visitors who desire a vehicle-free beach experience.</p>	<p><b>Impacts of the Alternative:</b>                      Those looking for an experience at the Seashore that includes ORV use would have long-term moderate adverse impacts as the designation of VFAs and the establishment of the SMAs would preclude ORV use, either seasonally or year-round, from some areas of the Seashore that are popular visitor use areas. Three SMAs under ML2 management procedures would provide an ORV pass-through corridor at the start of the breeding season, subject to resource closures, lessening the impacts to this user group. Additional recreational opportunities such as park-and-stay and SCV camping would provide long-term benefits. Those looking for a vehicle-free experience at the Seashore would experience long-term benefits as alternative E provides for designated year-round VFAs, as well as seasonal ORV closures in areas such as village beaches and some of the SMAs. Since night driving would be seasonally restricted, but allowed until 10:00 p.m., under alternative E, there would be long-term moderate adverse impacts to night skies due to the hours of night driving allowed, implementation of park-and-stay opportunities, with long-term beneficial impacts during times of seasonal night-driving restrictions.</p> <p><b>Cumulative Impacts:</b>                      Cumulative impacts would be long-term moderate to major adverse to ORV users, and long-term beneficial for visitors who desire a vehicle-free beach experience.</p>	<p><b>Impacts of the Alternative:</b>                      Those looking for an experience at the Seashore that includes ORV use would have long-term moderate adverse impacts as the designation of VFAs and carrying capacity limits could or would preclude ORV use, either seasonally or year-round, from some areas of the Seashore that are popular visitor use areas. Improved access would be provided to the soundside under this alternative as well. Those looking for a vehicle-free beach experience at the Seashore would experience long-term benefits as alternative F provides for year-round VFAs, as well as seasonal ORV closures in areas such as village beaches, two new pedestrian trails, 14 new or improved parking areas with pedestrian access, and pedestrian access seaward of prenesting closures (prior to observed breeding activity). Since night driving would be seasonally restricted under alternative F, there would be long-term negligible to minor adverse impacts to night skies, with long-term beneficial impacts year-round in VFAs and seasonally on ORV routes during times of seasonal night-driving restrictions.</p> <p><b>Cumulative Impacts:</b>                      Cumulative impacts would be long-term moderate to major and adverse to ORV users, and long-term beneficial for visitors who desire a vehicle-free beach experience.</p>

Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<p><b>Socioeconomic Impacts</b></p>	<p><b>Impact of the Alternative to the Region of Influence:</b> The region of influence (ROI) is expected to experience long-term negligible adverse impacts or long-term beneficial impacts depending on the extent of beach closures. The Seashore villages (the villages bordering the Seashore) would experience the majority of the impacts with the potential for larger short-term impacts to specific businesses that cater most directly to ORV users.</p> <p><b>Impact of the Alternative to Small Business:</b> Small businesses may experience long-term negligible to minor adverse impacts or long-term beneficial impacts depending on the extent of beach closures. Based on visitation statistics in 2007, there is a greater likelihood of negligible impacts.</p>	<p><b>Impact of the Alternative to the Region of Influence:</b> The ROI is expected to experience long-term negligible to minor adverse impacts depending on the extent of beach closures. The Seashore villages would experience the majority of the impacts with the potential for larger short-term impacts to specific businesses that cater most directly to ORV users. Based on the current visitation statistics, the probability of negligible impacts is greater than the probability of minor adverse impacts.</p> <p><b>Impact of the Alternative to Small Business:</b> Small businesses may experience long-term negligible to moderate adverse impacts depending on the extent of beach closures. Based on current visitation statistics there is a greater likelihood of negligible or minor impacts.</p>	<p><b>Impact of the Alternative to the Region of Influence:</b> The ROI is expected to experience long-term negligible to minor adverse impacts. The Seashore villages would experience the majority of the impacts with the potential for larger short-term impacts to specific businesses that cater most directly to ORV users. Efforts to improve access through pedestrian corridors, when compared to the no-action alternatives, and changes to access ramps would decrease the impacts on businesses that rely on visitors using the beaches affected by the new corridors and ramps relative to the no-action alternatives. However, the longer ORV closures in the fall months may reduce visitation under alternative C relative to the no-action alternatives and make the mid to high impact scenarios more likely.</p> <p><b>Impact of the Alternative to Small Business:</b> Small businesses may experience long-term negligible to moderate adverse impacts, with a greater likelihood of adverse impacts relative to the no-action alternatives due to increased fall ORV closures.</p>	<p><b>Impact of the Alternative to the Region of Influence:</b> The ROI is expected to experience long-term minor adverse impacts. The Seashore villages would experience the majority of the impacts with the potential for larger short-term impacts to specific businesses that cater most directly to ORV users. Compared to the other alternatives, alternative D provides the least access to the beach by ORVs resulting in larger projected adverse impacts.</p> <p><b>Impact of the Alternative to Small Business:</b> Small businesses may experience long-term moderate to major adverse impacts. The adverse impacts are projected to be larger relative to the other alternatives because of the limits on beach access for ORVs.</p>	<p><b>Impact of the Alternative to the Region of Influence:</b> The ROI is expected to experience long-term negligible to minor adverse impacts. Based on the visitation statistics for 2008, the probability of negligible impacts is greater than the probability of minor adverse impacts. The Seashore villages would experience the majority of the impacts. Like alternative B, alternative E provides for more ORV access and the impacts would likely be on the lower end of the range compared to alternatives C and D.</p> <p><b>Impact of the Alternative to Small Business:</b> Small businesses may experience long-term negligible to moderate adverse impacts, with a likelihood of adverse impacts in the lower end of the range relative to alternatives C and D due to increased ORV access. closures.</p>	<p><b>Impact of the Alternative to the Region of Influence:</b> The ROI is expected to experience long-term negligible to minor adverse impacts. The Seashore villages would experience the majority of the impacts with the potential for larger short-term impacts to specific businesses that cater most directly to ORV users. Alternative F provides less ORV access to the beach compared to the no-action alternatives, especially with 26 miles of the Seashore designated as year-round VFA. However, some popular areas, such as Cape Point, South Point and Bodie Island spit, would have designated year-round or seasonal ORV routes, subject to resource closures. There are more VFAs for pedestrians because of the ORV route designations, as well as increased parking for pedestrian access. Compared to the no-action alternatives, these measures could increase overall visitation and increase the probability that revenue impacts would be at the low end of the estimated range rather than the high end.</p> <p><b>Impact of the Alternative to Small Business:</b> Small businesses would experience long-term negligible to moderate adverse impacts. The extra efforts to increase ORV access and pedestrian access should increase the probability that the impacts are on the low rather than high end of the range.</p>

VUA	visitor use assistant

## CHAPTER 1: PURPOSE OF AND NEED FOR ACTION

This “Purpose of and Need for Action” chapter explains what this *Off-Road Vehicle Management Plan / Environmental Impact Statement* (plan/EIS) intends to accomplish and why the National Park Service (NPS) is taking action at this time. This plan/EIS presents four action alternatives for managing off-road vehicle (ORV) use and assesses the impacts that could result from continuing current management (the two no-action alternatives) or implementation of any of the action alternatives. Upon conclusion of this plan/EIS and decision-making process, the alternative selected for implementation will become the ORV management plan, which will guide the management and control of ORVs at Cape Hatteras National Seashore (Seashore) for the next 10 to 15 years. It will also form the basis for a special regulation to manage ORV use at the Seashore. Brief summaries of both the purpose and need are presented here; more information is available in the “Administrative Background” section of this chapter.

### PURPOSE OF THE PLAN

The purpose of this plan is to develop regulations and procedures that carefully manage ORV use/access in the Seashore to protect and preserve natural and cultural resources and natural processes, to provide a variety of visitor use experiences while minimizing conflicts among various users, and to promote the safety of all visitors.

### NEED FOR ACTION

Cape Hatteras National Seashore provides a variety of visitor experiences. It is a long, essentially linear park, visitation is high, and parking spaces near roads are limited. Some popular beach sites, particularly those near the inlets and Cape Point, are a distance from established or possible parking spaces. Visitors who come for some popular recreational activities such as surf fishing and picnicking are accustomed to using large amounts and types of recreational equipment that cannot practically be hauled over these distances by most visitors without some form of motorized access. For many visitors, the time needed and the physical challenge of hiking to the distant sites, or for some even to close sites, can discourage or preclude access by nonmotorized means. As a result, ORVs have long served as a primary form of access for many portions of the beach in the Seashore, and continue to be the most practical available means of access and parking for many visitors.

In addition to these recreation opportunities, the Seashore is home to important habitats created by the Seashore’s dynamic environmental processes, including habitats for several federally listed species including the piping plover and three species of sea turtles. These habitats are also home to numerous other protected species, as well as other wildlife. The NPS is required to conserve and protect all of these species, as well as the other resources and values of the Seashore. In addition, the Seashore was designated a Globally Important Bird Area by the American Bird Conservancy (American Bird Conservancy 2005). This designation recognizes those areas with populations and habitat important at the global level.

The use of ORVs must therefore be regulated in a manner that is consistent with applicable law, and appropriately addresses resource protection (including protected, threatened, or endangered species), potential conflicts among the various Seashore users, and visitor safety. Section 4.10(b) of the NPS regulations in Title 36 of the Code of Federal Regulations (CFR), which implements Executive Orders 11644 and 11989, prohibits off-road use of motor vehicles except on designated routes or areas. It

---

*Off-road vehicle  
(ORV) — Any  
motorized vehicle  
designed for or  
capable of cross-  
country travel on or  
immediately over land,  
water, sand, snow, ice,  
marsh, swampland, or  
other natural terrain.*

---

## Chapter 1: Purpose of and Need for Action

requires that “routes and areas designated for ORV use shall be promulgated as special regulations” in compliance with other applicable laws.

Therefore, in order to provide continued visitor access through the use of ORVs, the NPS must promulgate a special regulation authorizing ORV use at the Seashore. In order to ensure that ORV use is consistent with applicable laws and policies, the Seashore has determined that an ORV management plan is necessary as part of this process. Thus, the ORV plan and special regulation will:

- Bring the Seashore in compliance with Executive Orders 11644 and 11989 respecting ORV use, and with NPS laws, regulations (36 CFR 4.10), and policies to minimize impacts to Seashore resources and values.
- Address the lack of an approved plan, which has led over time to inconsistent management of ORV use, user conflicts, and safety concerns.
- Provide for protected species management in relation to ORV use by replacing the *Cape Hatteras National Seashore Interim Protected Species Management Strategy / Environmental Assessment* (Interim Strategy) (NPS 2006a), and associated Biological Opinion and amendments (USFWS 2006a, 2007a, 2008a) as modified by the consent decree.

## OBJECTIVES IN TAKING ACTION

Objectives are what must be achieved to a large degree for the action to be considered a success (NPS 2001a). All alternatives selected for detailed analysis must meet project objectives to a large degree and resolve the purpose of and need for action. Objectives must be grounded in the Seashore’s enabling legislation, purpose, significance, and mission goals, and must be compatible with direction and guidance provided by the Seashore’s general management plan, strategic plan, and/or other management guidance. The following are objectives identified by Seashore staff for developing this plan/EIS.

### MANAGEMENT METHODOLOGY

- Identify criteria to designate ORV use areas and routes.
- Establish ORV management practices and procedures that have the ability to adapt in response to changes in the Seashore’s dynamic physical and biological environment.
- Establish a civic engagement component for ORV management.
- Establish procedures for prompt and efficient public notification of beach access status including any temporary ORV use restrictions for such things as ramp maintenance, resource and public safety closures, storm events, etc.
- Build stewardship through public awareness and understanding of NPS resource management and visitor use policies and responsibilities as they pertain to the Seashore and ORV management.

### NATURAL PHYSICAL RESOURCES

- Minimize impacts from ORV use to soils and topographic features, for example, dunes, ocean beach, wetlands, tidal flats, and other features.

## **THREATENED, ENDANGERED, AND OTHER PROTECTED SPECIES**

- Provide protection for threatened, endangered, and other protected species (e.g., state-listed species) and their habitats, and minimize impacts related to ORV and other uses as required by laws and policies, such as the *Endangered Species Act* (ESA), the *Migratory Bird Treaty Act* (MBTA), and NPS laws and management policies.

## **VEGETATION**

- Minimize impacts to native plant species related to ORV use.

## **OTHER WILDLIFE AND WILDLIFE HABITAT**

- Minimize impacts to wildlife species and their habitats related to ORV use.

## **CULTURAL RESOURCES**

- Protect cultural resources, such as shipwrecks, archeological sites, and cultural landscapes, from impacts related to ORV use.

## **VISITOR USE AND EXPERIENCE**

- Ensure that ORV operators are informed about the rules and regulations regarding ORV use at the Seashore.
- Manage ORV use to allow for a variety of visitor use experiences.
- Minimize conflicts between ORV use and other uses.

## **VISITOR SAFETY**

- Ensure that ORV management promotes the safety of all visitors.

## **SEASHORE OPERATIONS**

- Identify operational needs and costs to fully implement an ORV management plan.
- Identify potential sources of funding necessary to implement an ORV management plan.
- Provide consistent guidelines, according to site conditions, for ORV routes, ramps, and signage.

## **PROJECT STUDY AREA**

The geographic study area for this plan/EIS is Cape Hatteras National Seashore in North Carolina (figure 1), unless otherwise noted under each resource topic.

## **PURPOSE AND SIGNIFICANCE OF CAPE HATTERAS NATIONAL SEASHORE**

All units of the national park system were formed for a specific purpose (the reason they are significant) and to conserve significant resources or values for the enjoyment of future generations. The purpose and

significance of the park provides the basis for identifying uses and values that individual NPS plans will support. The following provides background on the purpose and significance of the Seashore.

As stated in the Seashore's enabling legislation (the Act), Congress authorized the Seashore in 1937 as a national seashore for the enjoyment and benefit of the people, and to preserve the area. The Act states:

Except for certain portions of the area, deemed to be especially adaptable for recreational uses, particularly swimming, boating, sailing, fishing, and other recreational activities of similar nature, which shall be developed for such uses as needed, the said areas shall be permanently reserved as a primitive wilderness and no development of the project or plan for the convenience of visitors shall be undertaken which would be incompatible with the preservation of the unique flora and fauna or the physiographic conditions now prevailing in this area.

The Act also states:

...when title to all the lands, except those within the limits of established villages, within boundaries to be designated by the Secretary of Interior within the area of approximately one hundred square miles on the islands of Chicamacomico [Hatteras], Ocracoke, Bodie, Roanoke, and Collington, and the waters and the lands beneath the waters adjacent there to shall have been vested in the United States, said areas shall be, and is hereby, established, dedicated, and set apart as a national seashore for the benefit and enjoyment of the people and shall be known as the Cape Hatteras National Seashore.

A 1940 amendment to the enabling legislation authorized hunting and re-designated the area as the Cape Hatteras National Seashore Recreational Area. (Note: The history of the Seashore's name is described in more detail in the next section of this chapter.)

Park significance statements capture the essence of the park's importance to the nation's natural and cultural heritage. Understanding park significance helps managers make decisions that preserve the resources and values necessary to the park's purpose. The following significance statements recognize the important features of the Seashore. As stated in the 2006–2011 Strategic Plan, the Seashore has the following significance (NPS 2007b):

This dynamic coastal barrier island system continually changes in response to natural forces of wind and wave. The flora and fauna that are found in a variety of habitats at the park include migratory birds and several threatened and endangered species. The islands are rich with maritime history of humankind's attempt to survive at the edge of the sea, and with accounts of dangerous storms, shipwrecks, and valiant rescue efforts. Today, the Seashore provides unparalleled opportunities for millions to enjoy recreational pursuits in a unique natural seashore setting and to learn of the nation's unique maritime heritage.

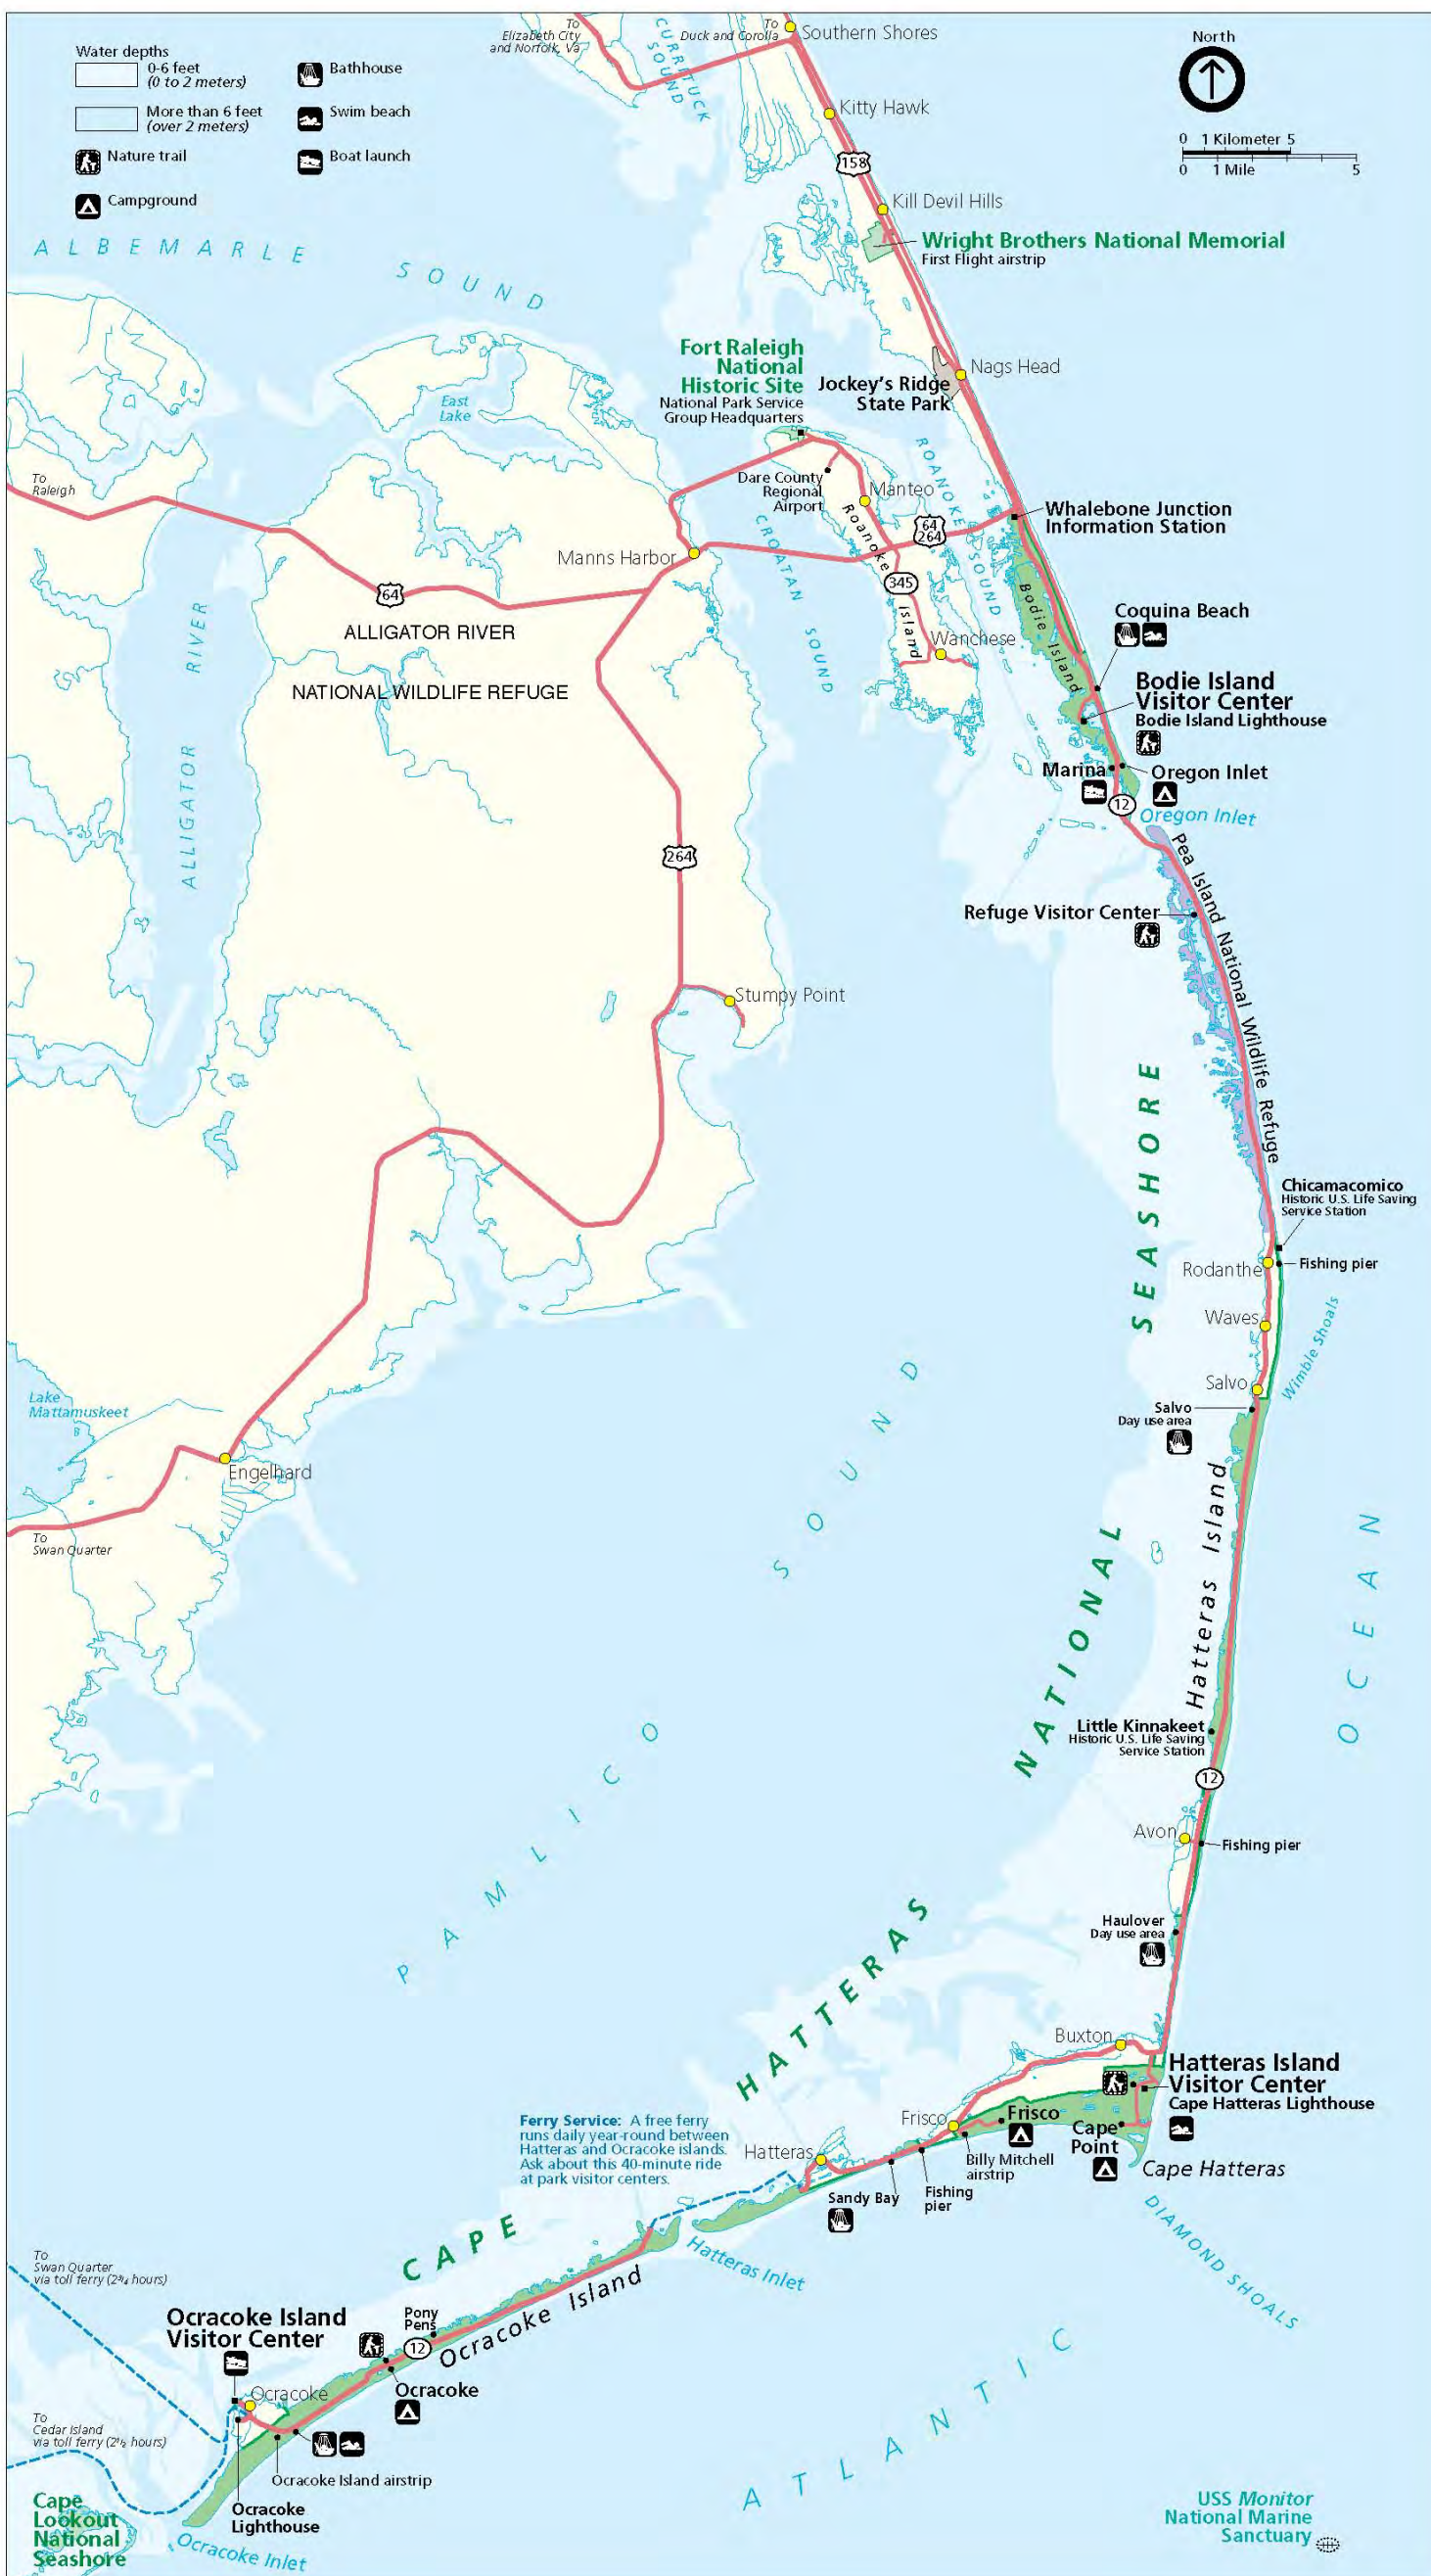

FIGURE 1. CAPE HATTERAS NATIONAL SEASHORE MAP

## DESIRED FUTURE CONDITIONS FOR THREATENED, ENDANGERED, STATE-LISTED, AND SPECIAL STATUS SPECIES

Desired future conditions (also called management targets) describe what park resources will look like once management goals have been achieved. They derive first from the overarching requirement of the *Organic Act* to conserve wildlife without impairment for the enjoyment of present and future generations. To meet the *Organic Act* mandate, the NPS will manage the Seashore to provide habitat and other conditions necessary to support sustainable populations of these species at the Seashore. Second, desired future conditions derive from NPS responsibilities as a federal agency under the ESA and the NPS *Management Policies 2006* to conserve listed species and to contribute recovery goals for them. Finally, they originate from the NPS policy to manage the same for state-listed species and species of park management concern as for federally listed species to the extent possible.

Desired future conditions are also a learning tool in the context of periodic review and adaptive management. They provide the basis for evaluation of progress and for the research hypotheses set in the adaptive management plan. The process of developing the desired conditions points out what is known and unknown about the resource and where additional research and adaptive management are appropriate. A definitive methodology for developing desired future conditions does not exist. Desired conditions are highly variable and therefore are based on conservative estimates that consider species variability, habitat availability, and environmental factors that could affect the success of any colony or nesting individual. The adaptive management initiatives that accompany these desired future conditions address the research that the Seashore may conduct to determine the conditions under which recreational use may be managed to enhance visitor experience without adversely affecting the achievement and maintenance of the desired future conditions. In the context of this plan/EIS, the following definitions are applied to desired future conditions:

- **Short-term** means 10 years (or two 5-year periodic review cycles) after implementation of plan.
- **Long-term** means 20 years (or four 5-year periodic review cycles) after implementation of plan.

When desired future conditions for resources are met or exceeded, it may allow for more flexible management of recreational use, provided adverse impacts of such use are effectively managed and wildlife populations remain stable. The populations of protected species that meet or exceed the goals set forth in this section would continue to be protected in accordance with applicable federal and state laws and regulations. Where progress is not being made toward the attainment of desired future conditions, periodic review and adaptive management may result in increased restrictions on recreational use. The management targets below are consistent with and contribute to the goals set forth by existing conservation plans such as U.S. Fish and Wildlife Service (USFWS) recovery plans (USFWS 1996a, 1996b), the Southeastern Coastal Plains–Caribbean Region Report U.S. Shorebird Conservation Plan (Hunter et al. 2002), the Waterbird Conservation Plan for the Mid-Atlantic/New England/Maritimes Region (MANEM 2006), and A Conservation Action Plan for the American Oystercatcher (*Haematopus palliatus*) for the Atlantic and Gulf coasts of the United States, Version 2.0 (Schulte et al. 2007).

The NPS considers the desired future conditions to be realistic, sustainable targets for piping plovers (table 1), nesting sea turtles (table 2), seabeach amaranth (table 3), and sensitive species of shorebirds (tables 4 and 5) at Cape Hatteras National Seashore.

**TABLE 1. DESIRED FUTURE CONDITIONS FOR PIPING PLOVERS**

Variable	Short-Term Target	Long-Term Target	Source
Number of breeding pairs	15	30	Short-term target from highest number of pairs recorded at Cape Hatteras National Seashore (1989) and the Biological Opinion (USFWS 2006a) <sup>a</sup> ; Long-term target from the Piping Plover Recovery Plan (USFWS 1996a, appendix B)
Fledge rate	5-year average of 1.0 chick per pair	5-year average of 1.5 chicks per pair <sup>d</sup>	Short-term target from the Biological Opinion (USFWS 2006a); long-term target from the Piping Plover Recovery Plan (USFWS 1996a)
Depredation rate	5-year average rate of mammalian depredation of eggs is <10%	Same as short-term target	Adapted from the Piping Plover Recovery Plan (USFWS 1996a) <sup>c</sup>

<sup>a</sup> The information is in the 2006 Biological Opinion under: Effects of the Action, A. Piping Plovers, Nature of the effect (USFWS 2006a):

"The biologically appropriate measure of population impacts is not the size of the current remnant population, but rather the potential pairs and productivity foregone. The 15 pairs documented at the Seashore in 1989 and comparison of current habitat with 1989 aerial photos furnish empirical evidence of potential for a population of at least five times the current number [which was 3] (i.e., 15 pairs). However, the demonstrated population growth elsewhere in the range provides evidence that the potential contributions at the Seashore are two to four times that number (i.e., 30 to 60 pairs). The USFWS estimated carrying capacity for the Seashore to be [sic] 30 pairs. (See USFWS 1996a, appendix B. Actual population growth at many of the sites in other states has exceeded the projections made in this exercise.)"

<sup>b</sup> In the future, if the fledge rate target in the Piping Plover Recovery Plan is revised (e.g., revised for Southern Recovery Unit), the Cape Hatteras National Seashore target will be adjusted to conform to the recovery plan.

<sup>c</sup> Recovery Plan: Recovery Tasks – Section 1.42 recommends "Deploy predator exclosures to reduce egg predation where appropriate" and states, in part: "Rimmer and Deblinger (1990) found that 24 of 26 nests (92%) protected by exclosures hatched at least one egg, while only six of 24 (25%) unexclosed nests hatched at a Massachusetts site over four years. Melvin et al. (1992) reported 90% (26/29) hatching of exclosed nests versus 17% (4/24) for unexclosed nests at six sites on Outer Cape Cod, Massachusetts."

**TABLE 2. DESIRED FUTURE CONDITIONS FOR NESTING SEA TURTLES**

Variable	Short-Term Target	Long-Term Target	Source
Number of loggerhead nests	94 <sup>a</sup> nests with an average annual rate of increase of 2%	115 <sup>a</sup> nests with an average annual rate of increase of 2%	Adapted from 2008 Loggerhead Recovery Plan goal (NMFS and USFWS 2008)
Percent of North Carolina total sea turtle nests	5-year average of 10% of North Carolina total	Same as short-term target	From the Biological Opinion (USFWS 2006a)
Ratio of false crawls to nests	5-year average of 1:1 or less	Same as short-term target	From Dodd 1988
Number of nests relocated	5-year average of <30%; Minimize number of nests relocated for reasons other than "risk of daily overwash or well-documented risk of erosion"	Same as short-term target	From Godfrey pers. comm. 2008

<sup>a</sup> Targets are based on 2% annual rate of increase from 2004-2008 average of 77.2 nests. Rate of increase of 2% for the Northern Recovery Unit is identified in the recovery plan. Based on this approach, the 50-year projection is 201 nests.

**TABLE 3. DESIRED FUTURE CONDITIONS FOR SEABEACH AMARANTH**

Variable	Short-Term Target	Long-Term Target	Source
Number of suitable sites occupied by seabeach amaranth	Develop a seabeach amaranth restoration plan for 4 suitable sites <sup>a</sup>	At least 3 of 4 suitable sites are occupied for 5 consecutive years	From the Seabeach Amaranth Recovery Plan (USFWS 1996b)

<sup>a</sup> Suitable sites include Bodie Island Spit, Cape Point, Hatteras Inlet Spits (Hatteras Island Spit and North Ocracoke Spit) and Ocracoke Inlet Spits (Southern Ocracoke Island Spit).

**TABLE 4. DESIRED FUTURE CONDITIONS FOR AMERICAN OYSTERCATCHERS**

Variable	Short-Term Target	Long-Term Target	Source
Number of nesting pairs	5-year average of 30 nesting pairs	5-year average of 45 nesting pairs	Targets based on American oystercatcher conservation action plan (Schulte et al. 2007) and recent Cape Hatteras National Seashore data <sup>a</sup>
Fledge rate (chicks fledged per nesting pair)	5-year average of 0.40 chicks per pair or higher	5-year average of 0.50 chicks per pair or higher	3 % annual increase from current rate of 0.30
Depredation rate	Percentage of nests lost that can be directly attributed to depredation of 30% or less	Percentage of nests lost that can be directly attributed to depredation of 20% or less	Average depredation rates over last 5 years: nests=31.2%, chicks=51.4% (NPS 2009n). The desired future condition is to reduce depredation rates while recognizing some depredation will continue to occur.

<sup>a</sup> From page 11 of the conservation action plan (Schulte et al. 2007): "We recommend that the population be stabilized and then gradually increased from its current level to at least 1.5 times its current size."

**TABLE 5. DESIRED FUTURE CONDITIONS FOR COLONIAL WATERBIRDS**

<b>Variable</b>	<b>Short-Term Target<sup>a</sup></b>	<b>Long-Term Target<sup>b</sup></b>	<b>Source</b>
Annual peak number of least tern nests	5-year average of 462 nests	5-year average of 577 nests	Long-term target equals 2009 peak count. Short-term target is mid-point between recent average (2007-2010) and the long-term target.
Annual peak number of common tern nests	5-year average of 292 nests	5-year average of 533 nests	Long-term target equals the average number of nests that occurred in 1977-2004. Short-term target is the mid-point between recent average (2007-2010) and the long-term target.
Annual peak number of gull-billed tern nests	5-year average of 21 nests	5-year average of 40 nests	Long-term target equals the average number of nests that occurred in 1977-2004. Short-term target is the mid-point between recent average (2007-2010) and the long-term target.
Annual peak number of black skimmer nests	5-year average of 132 nests	5-year average of 244 nests	Long-term target equals the average number of nests that occurred in 1977-2004. Short-term target is the mid-point between recent average (2007-2010) and the long-term target.

<sup>a</sup>Short-term target is to achieve the midway point between the long-term target and the recent average of the data points from the Seashore's 2007 - 2010 counts.

<sup>b</sup>Except for least terns, the long-term target for the respective species is to achieve the average number of nests that occurred at the Seashore in 1977 – 2004. Least terns are currently nesting in greater numbers than the 1977-2004 average; therefore, the long-term target is to maintain a 5-year average count equal to the 2009 peak count.

## ADMINISTRATIVE BACKGROUND

### HISTORY OF CAPE HATTERAS NATIONAL SEASHORE

Officially authorized in 1937 along the Outer Banks of North Carolina, Cape Hatteras is the nation's first national seashore. Consisting of more than 30,000 acres distributed along approximately 67<sup>1</sup> miles of shoreline, the Seashore is part of a dynamic barrier island system. The Outer Banks of North Carolina formed as a result of changes in sea level, wave and wind action, and ocean currents. These factors continue to influence the islands today through the processes of erosion and accretion of the shoreline; overwash across the islands; and the formation, migration, and closure of the inlets (NPS 1979). Since the 1930s, these natural processes have been influenced by human actions such as building sand berms<sup>2</sup> to protect roads and homes, dredging inlets, and filling inlets newly created by storms.

The story of the creation of Cape Hatteras National Seashore is documented in the Seashore's administrative history, *The Creation and Establishment of Cape Hatteras National Seashore* (NPS 2007f). No national park is suddenly brought into being except by a chain of milestones that lay the basis for an act of Congress or a presidential proclamation (NPS 2007f).

On June 23, 1936, President Roosevelt signed an "act to authorize a study of the park, parkway, and recreational area programs in the United States, and for other purposes" (49 Stat. 1894). The *Park, Parkway, and Recreational Area Study Act of 1936* significantly expanded the range and type of lands that could be preserved and managed by the NPS. The Act recommended specific additions to the national park system to provide recreational opportunities. The national recreation study led the NPS to establish four new types of parks in the park system: Recreational Demonstration Areas, national parkways, national recreation areas, and national seashores. Supporters of the park, parkway and recreation study, which included much focus upon the protection and use of coastal areas for recreational purposes, saw Cape Hatteras as the foremost example of a possible seashore recreational park. Concurrent congressional interest in erosion control, as demonstrated by the passage of the *Beach Improvement Act* in June 1936, also motivated interest in a national park in the Outer Banks. Undoubtedly, the recreational study and erosion control acts of 1936 spurred Congressman Lindsay C. Warren, who represented Dare County from 1925 to 1940, to begin work on "an act to provide for the establishment of the Cape Hatteras National Seashore" (NPS 2007f). Representative Warren introduced the

---

*The enabling legislation provides that the administration, protection, and development of the national seashore shall be exercised under the direction of the Secretary of the Interior by the NPS, subject to the provisions of the Organic Act.*

---

<sup>1</sup> Due to the dynamic nature of the barrier island system, the mileage of shoreline in the Seashore is constantly changing. This mileage estimate includes ocean shoreline and some interdunal roads managed for public recreation by the NPS. Actual on-the-ground mileage may vary, especially around the inlets and spits, due to the increased potential for erosion and accretion in these areas.

<sup>2</sup> The word "berm" as used in this document refers to remnants of the man-made dune or dune ridge originally constructed in the 1930s by the CCC and the Works Progress Administration. NPS actively maintained this dune ridge until the early 1970s when NPS ended the dune stabilization policy after scientists concluded that the man-made berms constructed since the 1930s had actually served to foreshorten the seashore's beaches and dramatically altered both the ecological and the topographical characteristics of the Outer Banks (NPS 2007f). "Berm" includes the man-made dune or dune ridge constructed to protect state highway NC-12 and interior sections of the island from ocean flooding and overwash during storms.

legislation in May 1937. It was subsequently approved by the House on August 2 and the Senate on August 14, then signed (50 Stat. 669) by President Roosevelt on August 17, 1937 (NPS 2007f).

In addition to articulating the recreation and preservation mission of the Seashore as stated in the “Purpose and Significance of Cape Hatteras National Seashore” section of this chapter, the enabling legislation provided that the administration, protection, and development of the national seashore shall be exercised under the direction of the Secretary of the Interior by the NPS, subject to the provisions of the *Organic Act*. It also provided that the legal residents of the villages shall have the right to earn a livelihood by fishing within the boundaries of the Seashore. The Act provided that the United States shall not use appropriated funds to purchase lands within the area, but such lands shall be secured by the United States only by public or private donation<sup>3</sup>. The Act authorized the Secretary to accept donations of land and funds to purchase lands, and to establish the national seashore contingent upon the acquisition of a minimum of ten thousand acres within the designated seashore area and provided that if such lands were not conveyed to the United States within ten years of the passage of the Act, the establishment of the national seashore may, at the discretion of the Secretary, be abandoned (NPS 2007f).

In March 1938, the NPS published the Prospectus of Cape Hatteras National Seashore in response to numerous requests for information concerning the area, which included the following recommendations for selection, use and development of the area (NPS 1938):

Inasmuch as the proposed Cape Hatteras National Seashore is the first area of its kind to be authorized by Congress, the National Park Service has adopted the following policy to be used in the selection, development and operation of this and other similar areas which may be acquired later.

Primarily a seashore is a recreation area. Therefore in its selection, the boundaries should be placed in such a manner that the maximum variety of recreation is provided. Thus while provision for bathing may be the first consideration of these areas, it must be kept in mind that a far greater number of people will be more interested in using a seashore area for other recreational purposes. It is desirable therefore to provide ample shoreline for all types of beach recreation. The Cape Hatteras National Seashore provides such an area in that there is extensive shoreline for all forms of recreation both for immediate use and for future development.

Secondarily, the area should include adjacent lands which by reason of historical, geological, forestry, wildlife, or other interests, have sufficient justification to be preserved by the Federal Government. It is important therefore to reach back into the hinterlands and acquire areas which will provide a variety of interests, scenic, scientific and historic. This principle has been followed in determining the boundaries of Cape Hatteras National Seashore.

Thirdly, it is important to include in the area, lands necessary for proper administration and lands which serve principally as a protection for the recreational and other developments which are the primary purpose of this area. Inasmuch as the Cape Hatteras National Seashore area is composed of islands and peninsulas, the land area in most cases is circumscribed by water, which fact in itself offers considerable protection. Inasmuch as control of much of the water in the Sounds may be desirable for fish and bird life, the

---

<sup>3</sup> In March 1939, the North Carolina General Assembly created the North Carolina Cape Hatteras Seashore Commission to acquire seashore lands for eventual transfer to the federal government (NPS 2007f).

boundaries of Cape Hatteras National Seashore area will embrace a substantial portion of these waters.

The development and operation of the Seashore area shall follow the normal national park standards with the understanding that recreational pursuits shall be emphasized to provide activities in as broad a field as is consistent with the preservation of the area. It shall be the policy of the Service to permit fishing, boating and other types of recreation under proper regulations and in designated areas where such activities may not conflict with other factors of greater importance. Where natural landing fields occur, the use of land and sea planes may be permitted where not in conflict with the interests of wildlife or inconsistent with proper development and use of the area.

At the time, the NPS had envisioned the Seashore to incorporate lands and waters including portions of Currituck Sound, Nags Head, Roanoke Island, Bodie Island, Hatteras Island and Ocracoke Island. While certain sites were targeted for development of recreational facilities, certain sections were identified to remain undeveloped and preserved as the “primitive wilderness” that existed at that time. Such plans for general development were as described in the prospectus (NPS 1938):

While further study and planning is required, it is expected that intensive development for recreational purposes shall be undertaken on the Bodie section which is the portion of the area between Oregon Inlet and the Whalebone Inn. In this connection, arterial and subsidiary roads and facilities for bathing, fishing, boating, camping, and hiking probably will be provided in this section.

Other development which will be of secondary priority will be in the Nags Head section where provision may be made for a more appropriate and interesting entrance road and where facilities for bathing on Roanoke Island and for hiking, picnicking, fishing and boating may be made available. The Nags Head and Bodie sections are the most accessible and offer opportunities for all varieties of recreation which should be adequate to the needs of the public for many years.

The Currituck, Hatteras and Ocracoke sections will remain in their natural conditions with no development other than for administrative purposes. It is possible some additional accommodations will need to be provided for visitors to the Cape Hatteras Lighthouse and that some alterations will be required in the plans for the area which is now a State park (*Cape Hatteras State Park*). It is definitely the desire of the National Park Service that the section between Oregon Inlet and Hatteras Inlet remain in its natural condition without any roads so that future generations may see this and other undeveloped sections as they are in our day.

In the years after the enabling legislation was passed, a number of issues and local concerns arose that ultimately changed the early NPS vision for the Seashore and which complicated and delayed land acquisition and formal establishment. One such concern included whether or not hunting would be allowed to continue once the national seashore was established. On June 29, 1940, Congress amended the 1937 authorizing legislation for Cape Hatteras National Seashore to permit hunting. The amendment specifically referred to compliance with the MBTA. This provision would later be key in determining how the NPS actually interpreted “hunting” within the Seashore, but perhaps for the first time in the history of the NPS, legal hunting was now authorized within a national park. The same amendment also changed the formal title of the park to “Cape Hatteras National Seashore Recreational Area.” The term “recreational area” in the 1940 amendment was derived clearly from the Secretary’s justification to allow hunting and by the Service’s desire to limit the setting of any precedent for more traditional types of

parks. However, the NPS had already defined a “national seashore” as a recreational area in its 1937 brochure explaining the *Park, Parkway, and Recreational Study Act* and the anticipated recreational purposes of the park were established by Congress through Acting Secretary Chapman’s letter to the House Committee on Public Lands. Thus, including the term “recreational area” in the title was redundant. In 1954 the NPS authorized the original park name (“national seashore”) to be used for all administrative purposes except for formal memoranda and documents requiring the full legal name. Subsequently, the term “recreational area” fell from use in most official references to the park (NPS 2007f). In 1961, Congress authorized Cape Cod in Massachusetts as the second “national seashore” and subsequently created eight more “national seashores” between 1962 and 1975 for a total of ten. All such park units that followed Cape Hatteras were officially named “national seashores.” Since 1962, Cape Hatteras has been referred to as “national seashore” in Congressional legislation and “national seashore” has been the standard nomenclature for this type of park.

As envisioned in the 1930s, the NPS had hoped to preserve a far more natural environment than it was forced by compromise to accept in the 1950s (NPS 2007f). In 1952, fifteen years after he submitted the act to create Cape Hatteras National Seashore, former Congressman Lindsay C. Warren offered what may be the purest surviving expression of his intent in doing so: “When I introduced the bill for the Cape Hatteras National Seashore in 1937, I would have nothing to do with it unless the people were fully protected forever in their hunting and fishing rights, and unless there was a guarantee of a hard-surface road if the Government came into the picture, and unless all of the villages were exempt. At that time there was very little prospect for a paved road, but I extracted a promise from the NPS that they would favor such a road to be built, whenever possible, either through State or Federal Aid funds. Frankly, I think that this Park will mean more to the people of Dare County than anything that could ever happen to them. I do not say that because I was the author of the bill, but I say it because I had studied the history of all Parks, before I came into the picture back in 1937” (NPS 2007f).

In September 1952, Director Wirth acted to address serious criticism of the NPS and its failure to provide adequate information about the seashore project to inhabitants of the Outer Banks. At a meeting of the North Carolina Cape Hatteras Seashore Commission, he announced plans to visit the area in early October specifically to talk personally with anyone who was willing to do so, which included meeting with the villagers of Hatteras and Ocracoke Islands (NPS 2007f). The concerns that were expressed at those meetings included: (1) uncertainty about where the Seashore boundary would be drawn around the villages and whether there would be enough room left for community expansion; (2) concern about the rights of individuals to continue commercial and sport fishing; (3) concern as to whether present hunting rights would be affected; and (4) concern that once the Seashore is established, the local people would be denied access to the ocean beach (NPS 2007f).

On October 31, 1952, at the request of Director Wirth, D. Victor Meekins, who had headed the Cape Hatteras National Seashore Commission until 1945 and later became editor of *The Coastland Times*, published a special edition of the newspaper showing NPS maps and statements and assured Wirth that “every family within the project, whether a subscriber of the newspaper or not, got a copy.” In an open letter from the Director addressing all those affected by the proposal to create Cape Hatteras National Seashore, Wirth laid out the plans and intent of the NPS and made certain key promises (NPS 2007f).

Wirth outlined park boundaries that had been adjusted to address some of the concerns of residents that he had heard during his three-day tour. Once again, the total size of the park was reduced, this time to 28,500 acres. The new boundary left more room for expansion of the villages toward the ocean, which had been a major complaint, but left the beaches under NPS control. Wirth said the NPS would need “on the ocean side of the towns, only those lands along the ocean which are necessary to protect and control the sand dunes, to reestablish them where necessary, and hold them to protect the communities from the intrusion of the ocean.” The boundaries were also closer to the Pamlico Sound shoreline. The new tighter

boundaries recognized that, under the basic legislation authorizing the Seashore, fishing and hunting rights were reserved to the people. That being the case, there was no real need to include Pamlico Sound waters in the Seashore since state and federal fishing and hunting laws and regulations would still apply to waters both inside and outside the Seashore boundaries. Wirth simply set an arbitrary distance of 150 feet that would allow hunters and fishermen to clearly know when they were in or out of the park (NPS 2007f).

Residents had been concerned with beach access, as well. On this account, in the letter Wirth plainly stated that the Seashore would be a public park open to all, including those of the Banks and visitors. “However,” he stated, “it will be necessary to establish certain regulations, such as to designate places for vehicles to get to the beach, in order to reduce sand dune erosion to a minimum; to manage ocean fishing where large numbers of bathers are using the beach; and to confine bathing to certain areas. These

**Surf Fishing, 1935**

Credit: NPS

latter are safety measures, as it would be dangerous to permit surf fishing where there are large numbers of people in bathing and, likewise, fishermen would not want bathers to interfere with their fishing.” For the future, Wirth noted “the National Park Service proposes to resume the sand fixation work; to re-establish the natural plant and wildlife within the area; and to provide access to the beach for everybody.” Wirth’s “Letter to the People of the Outer Banks” effectively countered the disinformation campaign waged by park opponents, laid out a clear vision of NPS management of the national seashore, and created a key document that was later often solemnly referenced by local residents in discussion with NPS officials on park matters (NPS 2007f).

Late in 1952 agreement was reached on the final boundaries of the Seashore area and in December 1952 the state-owned lands in the Seashore were transferred to the United States. In January 1953, Wirth recommended that Secretary of the Interior Oscar L. Chapman approve an order, consistent with Section 4 of the Act of August 17, 1937, directing that certain lands on the Outer Banks of North Carolina be “administered, protected, and developed by the National Park Service for national seashore recreational purposes for the benefit and enjoyment of the people.” This order, dated January 12, 1953, marked the formal establishment of the Seashore (NPS 2007f).

Federal land ownership extends from ocean to sound across three barrier islands—Ocracoke, Hatteras, and Bodie (figure 1). The eight villages are excluded

**High Tide on Ocracoke, 1936**

Credit: NPS

from the Seashore boundaries. On the oceanside of the villages, federal ownership was established as a 500-foot strip measured landward from the mean low water at the time of acquisition. A larger area seaward of Buxton and Frisco includes portions of Buxton Woods. The 5,880-acre Pea Island National Wildlife Refuge, approximately 12 miles long and located at the northern end of Hatteras Island, lies within the Seashore boundary and is administered for refuge purposes by the USFWS in accordance with the *National Wildlife Refuge System Improvement Act of 1997* (USFWS 2006b). ORV use is not allowed in the refuge, but the 12 miles of ocean shoreline are generally open to pedestrian use, except when localized closures are in effect to protect shorebird and sea turtle nesting areas. This plan/EIS does not include the area within the refuge.

Today the Seashore serves as a popular recreation destination with more than 2.1 million visitors in 2008 (NPS 2008e), showing an 8-fold increase in visitation since 1955 (NPS 2007f). Seashore visitors participate in a variety of recreational activities, including beach recreation (sunbathing, swimming, shell collecting, etc.), fishing (surf and boat), hiking, hunting, motorized boating, nonmotorized boating (sailing, kayaking, canoeing), nature study, photography, ORV use (beach driving), shellfishing, sightseeing, watersports (surfing, windsurfing, kiteboarding, etc.), and wildlife viewing. Seashore visitors use ORVs for traveling to and from swimming, fishing, and surfing areas, and for pleasure driving. Over the past five years (2004–2008), visitation to the Seashore has averaged approximately 2.2 million visitors per year (NPS 2008e).

Current management practices at the Seashore allow ORV users to drive on the beach seaward of the primary dune line. Drivers must use designated ramps to cross between paved roads (such as North Carolina Highway 12 [NC-12]) that run behind the primary dune line and the beach. In some areas, NC-12 provides a way around full beach closures or areas where the high tide line limits beachfront access. In addition to a multitude of visitor opportunities, the Seashore provides a variety of important habitats created by its dynamic environmental processes, including habitats for the federally listed piping plover; sea turtles; and one listed plant species, the seabeach amaranth. The Seashore contains ecologically important habitats such as marshes, tidal flats, and riparian areas, and hosts various species of concern such as American oystercatcher, Wilson's plover, red knot, and colonial waterbirds, including the state-listed (as threatened) gull-billed tern.

## SUMMARY OF OFF-ROAD VEHICLE USE AND MANAGEMENT AT CAPE HATTERAS NATIONAL SEASHORE

The legislation creating Cape Hatteras National Seashore did not specifically mention motor vehicle use or beach driving; however, the administrative history (NPS 2007f) contains numerous references to ORV use and related issues and concerns. The Act did, however, clearly establish the mandate for NPS to administer and protect the Seashore consistent with the *Organic Act* and the purposes for which the Seashore was established.

Before 1954, local residents and visitors drove on the beaches at the Seashore because there were few formal roads in this remote area. Historically, the main purpose of beach driving was transportation, and not recreation. Because the area was sparsely populated, the number of ORVs on the beach was much smaller than it is today. In 1954, NC-12 was paved, providing a formal transportation route. The paving of NC-12, the completion of the Bonner Bridge connecting Bodie and Hatteras islands in 1963, and the introduction of the State of North Carolina vehicle ferry system to Ocracoke Island facilitated visitor access to the sound and ocean beaches and resulted in increased vehicle use on beaches for recreational purposes (NPS 2004a). Residents adopted the use of ORVs for commercial netting of fish, while sport fishermen used ORVs to pursue migrating schools of game fish and reach more productive areas, such as Cape Point or the inlets, often a mile or more from the nearest paved surface. Presently, ORVs are used for activities such as commercial and recreational fishing, sightseeing, travel to and from swimming and surfing areas, and pleasure driving (NPS 2004b).

In 1937, then NPS Assistant Director for Land Planning, Conrad L. Wirth, published an eloquent description of the primitive qualities of the Outer Banks at a time when much of the area could still not be reached by road. In fact, at the automobile service station at Whalebone, which was a small shack distinguished by the huge skeleton of a whale propped up nearby, the road south to Cape Hatteras simply ended. “Here,” Wirth wrote, “the pavement swings to the right and leads into the village of Manteo about six miles to the west. Now you are at the point where the primitive begins. You drive off the road onto the sand, stop, and let about half of the air out of your tires, because the rest of the driving will be over the almost trackless beach” (NPS 2007f).

A similar description was written by Thomas W. Morse, Assistant in Charge of North Carolina State Parks. In the 1937 Master Plan Report for Cape Hatteras State Park, Morse stated, “...no major roads enter this area and it is reached by driving almost fifty miles over the sands from the Whale Bone Filling Station, south of Nags Head to the park. This trip involves crossing Oregon Inlet by ferry. While it is agreed that this method of entry is of great aesthetic value, it should be pointed out that it also involves considerable destruction of wildlife because of promiscuous driving” (NCD CD 1937).

This was how things remained until the late 1940s, when paved roads were first built to connect some of the villages on Hatteras Island. Later, NC-12 was completed south from Whalebone to the ferry at Oregon Inlet, and in late 1952 a road was completed from there through Pea Island to the village of Hatteras. The romantic trail Wirth had followed in 1937 was nothing but a memory, and “Whalebone Station,” sans the bones and station, had become “Whalebone Junction.” If Wirth regretted this loss—as did at least a few residents of the Outer Banks—he was willing, if not eager, to push the key improvements in public access that facilitated the Seashore’s establishment, seeing that improved access reinforced the Seashore’s success (NPS 2007f).

When Conrad L. Wirth became Director of the NPS in December 1951, he faced a park system severely taxed by the postwar travel boom, fueled by increasing personal incomes, leisure time, and automobile ownership. Visits to the national parklands mushroomed from 6 million in 1942 to 33 million in 1950 and 72 million in 1960. With few improvements since the Civilian Conservation Corps (CCC) era, the

deteriorating park roads, campgrounds, employee housing, sanitary systems, and other facilities were overwhelmed. Director Wirth's response to the increasing park problems was to initiate "Mission 66," a ten-year program to upgrade facilities, staffing, and resource management throughout the system by the 50th anniversary of the NPS in 1966 (NPS 1990).

In September 1953, Chief Park Ranger G. P. Hultman, in reviewing a field-operations manual, made several cogent observations about security and conservation at the Seashore and how to further these through interpretation. Many factors limited his recommendations, including that the land acquisition program was far from complete and that wildlife and waterfowl protection, including hunting, was an unsettled issue, and, therefore, "ultimate problems cannot be visualized." Hultman was nevertheless insightful in observing that commercial development over the previous decade had greatly reduced the area available for public seashore recreation, that plant growth was far more extensive than during the era of grazing, and that "the power and changing characteristics of sea and wind seem to be greatly underestimated." Moreover, Hultman recognized that "driving conditions, including sand and water on the very pavement serving as access to the area, are aggravated by unlimited access to the beach" and the ability of park visitors to drive off-road at will were likely to become an increasing problem (NPS 2007f).

On March 8, 1954, Allyn F. Hanks arrived at Cape Hatteras to assume his duties as the first operational superintendent of the Seashore (NPS 2007f). In April 1955, Superintendent Hanks submitted to Director Wirth and his "Mission 66 Committee" a draft of the policies and practices that should guide the Mission-66 program at Cape Hatteras National Seashore. Hanks thought increased visitation would eventually link most, if not all, of the islands of the Seashore. North Carolina was making important transportation improvements during the period of Mission 66 both around Pamlico Sound and along the Outer Banks, including the construction of major roads and bridges. Hanks therefore predicted visitation at the Seashore would reach two million by 1966, and as a result, he said, "it will become increasingly difficult to preserve unimpaired primitive wilderness conditions." While roads would fulfill the NPS promise to provide public access and economic opportunities for local residents, roads would also put millions of visitors within a day's drive of the Seashore and give them easy access to its natural areas. Hanks worried that motor vehicle use would conflict with recreational pursuits and preservation (NPS 2007f).

**Beach fishing 1956**

Credit: NPS

In the prospectus, Hanks laid out the Seashore's significance, as well as its needs in protection, interpretation, development, and operations. His plans encouraged park development near the villages for the convenience of the public, to promote village growth, and to concentrate development thus leaving miles of beach front undisturbed. In the end, Hanks' prospectus determined the location and layout of most major developments at the Seashore, including the fishing piers and camping sites. The Mission 66 prospectus also encouraged the development of a roadway along the entire length of the Seashore. Although the agency now acknowledged the popularity of roads, it sought to use them to channel traffic from

more sensitive areas in the Seashore. Wirth approved the Mission 66 prospectus for Cape Hatteras National Seashore on November 15, 1956 (NPS 2007f).

During Mission 66, the impact of driving on the beaches was a major concern. The Mission 66 prospectus stated, “The beach, as the area’s most significant resource, and the narrow margin which is the locale for man’s numerous activities, requires development planning that will promote use only by people on foot. Vehicular use must be rigidly controlled and permitted only under specified conditions” (NPS 1956). Superintendent Hanks declared, “driving along the ocean shore by the public must be controlled.” To reduce its impact on the recreational purposes, the park was established to meet, specifically picnicking, swimming, and surf-casting, all of which “require assurance of non-intervention by shore driving.” Hanks further noted, “such protection has long been recognized by the more developed areas north to Kitty Hawk.” There, local property owners had restricted beach driving because of the damage it caused. Hanks thus planned to limit driving, even by NPS personnel, except for emergencies. In addition, during Mission 66, the NPS was dedicated to maintaining its barrier dune system in the Outer Banks, and Hanks sought to limit “indiscriminate access over the dunes to the ocean where in the past has been a large contributing factor in deterioration of the original barrier dune. Such practice must be curtailed to obtain overall greater protection benefits.” At the same time, Hanks acknowledged that minimum shoreline driving and limited access over the dunes “must be flexible to allow commercial fishing in general as provided for in the original Act.” Because shoreline driving negatively affected recreational activities, the Superintendent told Director Wirth, “it may be necessary, however, to exclude commercial fishing from certain portions of the Seashore by Secretarial Order to protect those portions for recreational use.” NPS policy was to protect the dunes from damage and to provide for recreational needs, which meant that vehicle use along some portions of the beach had to be entirely excluded. In other areas, access would have to be allowed for commercial fishing by local residents using, for example, “haul nets” that required motorized power (NPS 2007f).

Mission 66 brought much development to Cape Hatteras National Seashore, even if some stretches of beach were left undeveloped. As envisioned in the 1930s, the NPS had hoped to preserve a far more natural environment than it was forced by compromise to accept in the 1950s. By then, the practical necessity for fairly robust park development to meet the needs of large beach crowds and other visitors brought in on modern roads and bridges was greatly increased. The need to accommodate large crowds demanded infrastructure, a reality that few contested (NPS 2007f). In March 1957, Superintendent Hanks issued a summary of the Mission 66 prospectus that re-emphasized that most other facets of the park’s development were “dependent upon success in the field of erosion control” (NPS 2007f). In September 1958, a major management review was conducted at the Seashore. The review was generally positive but it recommended that a revised Mission 66 prospectus be completed after the final master plan and interpretive development plan, both undergoing review, were completed. Among a number of findings, the review also determined that the park urgently needed to place vehicular access ramps that would allow commercial fishermen access to the beach and stop them from building their own makeshift access points (NPS 2007f).

Between 1955 and 1958, the NPS completed major developments that established the Seashore’s basic recreational infrastructure (NPS 2007f). The new facilities, along with the completion of NC-12 on Hatteras Island in 1954 and on Ocracoke Island in 1957, contributed to more than doubling park visitation between 1955 and 1961 (NPS 2007f). After the highway was completed, a major problem was the bottleneck at Oregon Inlet where a fast-growing volume of visitors quickly overran the existing state ferry operation. Eventually, congestion at the bottleneck of Oregon Inlet became so bad that a bridge was the only solution. Because the traffic jams caused such a problem for the NPS, and because a bridge would benefit other federal agencies working on the Outer Banks, Congress authorized the NPS to help fund the needed bridge (NPS 2007f). On August 30, 1961, the NPS issued a press release discussing its support for congressional legislation that would allow the agency to help the State of North Carolina build a bridge across Oregon Inlet. The bill was submitted by Bonner on May 1, 1961, and sent to the whole House on August 28, 1961 (HR 6729). Bonner’s motivation was simple—the congestion at Oregon Inlet could not be alleviated by additional ferries. The NPS was interested in helping to pay for the bridge, which

reversed its early position, if for no other reason than the congestion generated frequent criticism both by the public and in the press. Traffic congestion also put pressure on NPS facilities north of the inlet. Cape Hatteras National Seashore was thought the only example of a park where the state maintained a road within the NPS system. The NPS acknowledged that such a bridge was a long-sought goal of the state and those living in the Outer Banks but was a cost beyond their means. NPS staff also realized the park and its visitors would benefit from the elimination of the bottleneck at Oregon Inlet. There were some minor complications, however, that may have been reminiscent of NPS sensitivity over the issue of wilderness preservation in the 1930s, when the NPS had hoped to preserve a vast expanse of wild seashore on the Outer Banks. Compromise was unavoidable, namely as a result of an NPS agreement to allow road construction, which was necessary to secure local support for the Seashore (NPS 2007f).

On October 11, 1962, Congress authorized funds for construction of a bridge to cross Oregon Inlet within Cape Hatteras National Seashore. The law (Public Law 87-79; 76 Stat. 909) allowed the Secretary of the Interior to pay \$500,000 toward the cost of the bridge as long as this amount came only from funds specifically designated for that purpose and the state agreed to pay for upkeep. The remainder of the costs would be borne by the federal government. Construction of the bridge over Oregon Inlet took approximately two years and made a huge impact on the village life of Hatteras Island and on the island's wild flora and fauna. Upon completion, the bridge brought in waves of tourists whose numbers increased with each passing year, an indisputable and considerable economic benefit to all the villages on Hatteras and Ocracoke islands. It was a windy day in early May 1964 when the new causeway linking Bodie and Hatteras islands was duly dedicated as the Herbert C. Bonner Bridge (NPS 2007f).

In some ways, the Bonner Bridge had taken as long to create as the park itself. It might even be said that neither would have been possible without the other, since to some extent, the existence of the park was predicated upon the faith of Outer Banks residents in the NPS to protect and promote their interests, which included both the preservation of an idyllic coastal recreation environment that attracted increased tourism and the development of transportation links between the remote islands and the outside world. Access was a key issue if the growing potential of a tourist-based economy was actually to be realized. In the years ahead, this fundamental dilemma, common to many national park areas, would pose great challenges to managers of Cape Hatteras National Seashore (NPS 2007f).

Well before the end of Mission 66, NPS officials understood that the beach management (i.e., dune stabilization) situation was dire. The NPS was waging a fight against a fundamental force of nature, but what was not crisply understood was the futile nature of that struggle and how a commitment to preserve a "primitive wilderness" had been transformed into a commitment to protect human-made structures using techniques that actually undermined the preservation of natural beaches. As the work continued to stabilize dunes, vehicular access to the beaches became a more pressing issue. In March 1963, Director Conrad Wirth and Rep. Herbert Bonner discussed the use of automobiles on beaches, specifically regarding vehicle ramps. Bonner had received complaints from local residents who wanted ramps set near their own property. By then, according to Wirth, eighteen ramps had been set up to allow commercial fishermen beach access, which Wirth said was prescribed by the law creating the Seashore. While these ramps had been set up to allow commercial fishermen to access the beach, Wirth said that the public could use the ramps also to gain access to the shore. According to Wirth, "past history has shown that each vehicular access is a vulnerable spot for the ocean to break through and cause extensive damage to the barrier dune and natural features of the area." "To provide more access would jeopardize NPS stabilization efforts," Wirth said, "while providing ramps near one private property owner would only inspire others to ask for similar access" (NPS 2007f).

Automobile driving on the beach was an infrequent topic in NPS and congressional correspondence from this period, but clearly the NPS viewed vehicular access to the beach as necessary to fulfill an obligation to allow continued commercial fishing by legal residents of the villages. This position, however, was an

interpretation of the law authorizing the Seashore and its amendments, since neither made specific reference to automobiles or how beach access would be provided. It only specified that commercial fishing by legal residents was to be allowed. One practice in use by local residents was “haul fishing,” a technique whereby fisherman used a jeep or similar vehicle to drag a net from the sea to the beach. Vehicle use was integral to this practice and not merely a means for transportation. The NPS established beach access ramps to enable commercial fishermen to continue to use vehicles to fish from shore while mitigating damage to the barrier dunes by controlling the points of entry, but these ramps also allowed general visitors motorized access to the beach (NPS 2007f).

Within a decade of completion of the Bonner Bridge, the NPS was facing serious public complaints on two related fronts. The first concerned the presence of ORVs or “beach buggies,” especially at Cape Point near the famous Cape Hatteras Lighthouse. Such vehicles, then mainly used by fishermen, concentrated near the best fishing sites in groups of up to fifty or so, leaving piles of beach trash and making it difficult for other visitors to enjoy the scenic vista. The problem may have existed for a while, but by 1972, as one writer informed Director George B. Hartzog, Jr., a person “literally could not take a photograph of the waves by themselves without two or three hip-booted intruders in the viewfinder.” This visitor did not want a total ban on the buggies but did want some restrictions. He protested that the NPS mission was to leave the land “unimpaired” and noted that if there were fifty buggies this year, when would it stop? “You might as well call it the Hatteras Parking Lot,” he concluded (NPS 2007f).

The stock NPS response was that “in contrast to natural areas, the recreation area is supposed to serve many needs.” Indeed, according to Deputy Assistant Director Joseph C. Rumberg, Jr., “a closure of the cape to allow full aesthetic appreciation of the power and wonder of the ocean, at the expense of fishing and beach buggy use, would be a matter fraught with controversy.” Nevertheless, Director Hartzog directed the Southeast Regional Office in Atlanta to arrange with the Superintendent to study the possibility of changes, limitations, or even the elimination of beach buggies. Hartzog hoped the study would develop recommendations that might provide the park with a better means of controlling vehicle use on the beach (NPS 2007f).

The problem was actually more serious than suggested by visitors annoyed over compromised scenic views. The Bonner Bridge had also brought increasing numbers of fishermen who were not residents of the Outer Banks but were bent on using more sophisticated means to exploit commercial opportunities. The basic issue involved fishermen using dories loaded with nets that were pulled along the beach by truck until a school of fish was located. Then, a boat was launched and part or all of the school was surrounded by the net tied to the truck onshore, which hauled in the line. According to the account of a sport-fishing newsletter, an existing practice became an acute problem by 1972. During the 1930s, only a half-dozen local residents practiced this technique, some using nets that were up to 200 yards long. Between 1936 and the early 1960s, the number of fishermen had remained fairly constant, and with up to ten such fishermen working, their nets were still no longer than 400 yards (NPS 2007f).

After the Bonner Bridge opened in 1964, however, commercial fishermen from elsewhere began participating in the fish harvest, some from as far away as New York. Now as many as twenty commercial fishermen were using nets up to sixteen hundred yards in length. This activity was wiping out striped bass because such huge nets took in 20- to 50-pound fish in catches weighing up to 10,000 pounds. Worse, non-commercial fish were merely left to die and rot on the beach. By 1972, the problem was acute, and local fishermen began to complain, noting that they brought in cash much needed by the villagers whereas outside commercial fishermen merely depleted the fishing stock. After several years of competition between these various groups of fishermen, the situation began to threaten violence, and calls for new legislation were voiced (NPS 2007f).

In the coming years, many heated debates were to erupt between commercial, sports, environmental, and park-access groups. It should be noted, however, that between the 1930s until well into the 1960s, the public lodged few complaints about fishing, beach driving, or conflicts between vehicle-users and other beach-goers. At first, the few Outer Banks residents with vehicles, and occasional visitors, did not relish the notion of beach driving and did so simply because there were almost no roads on which to drive. After World War II, improved automotive technologies allowed more villagers and visitors to drive along the seashore, but without roads this activity still entailed the onerous rituals of deflating and re-inflating tires, digging out from occasional sandpits, and risking getting stuck. Such experiences were unpleasant but whether they bothered the typical “Hatterasman” as writer Ben Dixon MacNeill phrased it, was another question (NPS 2007f).

Outer Banks residents were by tradition and necessity a people of the sea and were adept at using it for transportation. They did not need roadways for their own transportation or lifestyle needs, rather an absence of roads limited economic growth. As their traditional life ways declined, Outer Banks residents increasingly sought the roads and bridges needed to sustain a tourist-based economy. A major reason the NPS began to reappraise its opposition to an island parkway was that random beach driving led to destruction of the artificial dunes and harmed native flora and fauna. Ironically, the very road that boosted tourism and was supposed to better protect the environment by eliminating the chore of beach driving was also what made commercial and recreational access to the beach ever more possible and brought those separate interests into conflict. However, some commercial fishermen used jeeps early on to operate shore-based fishing nets while the NPS set up ramps to help channel sport fishermen away from the more sensitive dune areas. These early ramps also gave access to increasing numbers of tourists. Still, such uses did not begin to elicit great controversy until after the Bonner Bridge opened in 1964. With the bottleneck at Oregon Inlet removed, there was no limit to the number of park visitors who in a day’s span could drive down the banks and out onto the beach. Completion of the Bonner Bridge, therefore, marks a key demarcation point in the history of the first national seashore (NPS 2007f).

In brief, residents adopted the use of ORVs for commercial netting of fish, while sport fishermen used ORVs to pursue migrating schools of game fish and reach more productive areas, such as Cape Point or the inlets, often a mile or more from the nearest paved surface. Presently, ORVs are used to access the beach for activities such as commercial and recreational fishing, sightseeing, travel to and from swimming and surfing areas, and pleasure driving (NPS 2004b).

Today ORVs access the ocean beaches and sound shoreline via a system of “ramps” located off NC-12 and other paved roadways. The ramps began as an informal system of unimproved access points connecting the roadway to the sounds and beaches. Over time, this system was formalized and the oceanside ramps are now numbered, maintained, and identified on the Seashore’s ORV route maps as official vehicle access routes for beach access. In 1978 there were 28 identified ramps, 22 of which were located on NPS lands. Although the NPS opened a new ramp to the public in 1998, the number of ramps

has decreased since 1978 as some were lost to erosion and others were closed to the public and are now used for administrative vehicle access only (NPS 2004a). The NPS currently has 17 oceanside access ramps available for public ORV use (NPS 2008g).

ORV use at the Seashore has historically been managed since the 1970s through various draft or proposed plans, though none were ever finalized or published as a special regulation as required by Executive Orders 11644 and 11989 and 36 CFR 4.10. In 1973, in response to Executive Order 11644, Use of Off-Road Vehicles on the Public Lands (February 8, 1972), the Seashore developed a draft ORV management plan (NPS 2004b) that included the following:

- Designation of 27 beach access routes or ramps.
- Identification of a permitted area for travel from the toe of the dune to the ocean.
- License requirements for vehicles and operators.
- Closure of one heavily eroded section of the beach near the Cape Hatteras Lighthouse year-round.
- Designation of seasonal closures in five areas heavily used by pedestrians between May 26 and September 10.

This management plan was not finalized or published as a special regulation, as required by Executive Order 11644 and 36 CFR 4.10.

A few years later, in response to Executive Order 11989, Off-Road Vehicles on Public Lands (May 24, 1977), the NPS began developing a draft ORV management plan for the Seashore. In response to the plan, which was released in January 1978, the North Carolina Beach Buggy Association and the Outer Banks Preservation Association each issued proposed alternative plans for ORV management at the Seashore. These proposed plans were considered by the Seashore, along with public comment, and in November 1978 the Draft Interim Management Plan: Off-Road Vehicle Use, Cape Hatteras National Seashore was issued (NPS 1978a). It proposed guidelines for the management of ORV use at the Seashore while the general management plan was under development. The draft interim ORV management plan identified zones of use for ORVs, as well as described conditions under which vehicles would be allowed or prohibited. The proposed zones of use were as follows:

- Zone 1 – Ocean Beach: In this zone ORVs will be permitted landward from 150 feet of the existing tide line, but no closer than 20 feet to the toe of the dune or vegetation line. Portions of Zone 1 may be closed seasonally (May 15 through September 15), or closed temporarily to protect nesting birds or sea turtles, or when the distance between the existing tide and the toe of the dune or the vegetation line is reduced to less than 100 feet. Permits must be issued for vehicles that have less than four weight-bearing wheels and do not meet all vehicular licensing and inspection requirements of their state of origin.

- Zone 1(a) – Seasonally closed areas include those Zone 1 areas which, due to seasonal heavy pedestrian, swimming, wildlife or other uses, are deemed seasonally unsuitable for ORV use.

Seasonally closed areas shall be identified by signs at both ends of the area, and shall be indicated on maps available for viewing at the offices of the Superintendent and of each District Ranger.

Dates of seasonal closures shall be May 15 through September 15 of each year, except on Pea Island National Wildlife Refuge, where the Refuge Manager shall post such closures as he may find necessary to implement the regulations of the USFWS.

Seasonally closed areas shall consist of, but not be limited to, the following areas: Bodie Island, milepost 0 to milepost 3; beach areas fronting the villages of Rodanthe, Waves, Salvo, and Avon;

northern boundary of Buxton to one mile south of the Cape Hatteras Lighthouse; beach fronting the villages of Frisco and Hatteras; milepost 49 to milepost 54; and Ocracoke Island milepost 65 to 70.

- Zone 1(b) – Temporarily closed sections include:

Those narrow beach sections of Zone 1 that have decreased in width to the point where the average distance from the existing tide to the toe of the dune or vegetation line is less than 100 feet (30 meters). These sections shall be marked at each end by signs reading “Beach Temporarily Closed to Vehicle Traffic” and shall be indicated on maps available for viewing at the offices of the Superintendent and each District Ranger.

Bird Nesting Areas – Portions of high beach and inlet flats where significant bird nesting is occurring. These areas shall be temporarily closed to all visitor use and shall be marked by posts and “Bird Nesting Area” signs.

Sea Turtle Nests – Locations on the beach where a sea turtle nest is discovered. A rectangular section of beach that includes the nest with 300 feet (92 meters) of tide line seaward of the nest shall be temporarily closed to ORV use from dune to existing tide line. Closures shall be marked at both ends by posting with signs indicating “no ORVs – temporary turtle nest.” The period of closure shall begin on posting, 50 days after the turtle lays, and shall end 25 days later on official removal of the signs. The purpose of the closure is to protect hatchling loggerhead turtles, listed as “threatened” under the ESA.

- Zone 2 – Soundside: Marsh and flat land west and northwest of NC-12. Vehicular traffic shall be confined to marked trails, posted as open. No permit shall be required.
- Zone 3 – Buxton Woods, Open Ponds: The area of grassed dunes and forest lands lying between Headquarters, Cape Hatteras Group Coast Guard, and Frisco Campground. The area is roughly bounded on the south by the ocean dunes; on the east by a northeast-southwest trending line lying west of the Cape Point Campground, Coast Guard Group Headquarters, and NPS residence-maintenance area complex; on the north by the NPS boundary through Buxton Woods; and on the west by a south-north trending line lying east of the Frisco campground. In this zone, limited vehicular access on ORV routes posted as open shall be permitted only upon application in person to the Hatteras District Ranger (or designee) and there shall be no more than 30 total ORVs in this zone at any one time. Limited access permits for vehicular entry shall not exceed 24 hours in duration and shall not be issued more than 7 days in advance. Permits are renewable upon request except when vehicular capacity has been reached.
- Zone 4 – Dunes and Sand Plains: All land and dune areas seaward of the right-of-way of NC-12, except Zone 1 and Zone 3 lands. ORV operation is permitted only on trails posted for ORV use. Permits must be issued for vehicles that have less than four weight-bearing wheels and do not meet all vehicular licensing and inspection requirements of their state of origin (NPS 1978a).

The 1978 draft interim ORV management plan also called for a posted speed limit of 25 miles per hour and for ORV operators to possess a current driver's license from their state of origin. The permitting portion of the 1978 draft plan was controversial and was removed before release of the 1978 Draft Interim Management Plan: Off-Road Vehicle Use, Cape Hatteras National Seashore (NPS 1978a). Except for Zone 1, the 1978 draft plan stated that no vehicle would enter any unpaved dirt or sand trail or path, or follow any vehicular tracks not posted as an ORV trail. Though the draft plan was not finalized or published as a special regulation as required by Executive Orders 11644 and 11989 and 36 CFR 4.10, the Seashore implemented the following plan components:

- Consolidating and clearly marking entrance and exit points to soundside areas;
- Establishing sea turtle and bird nesting protection zones;
- Increasing efforts to provide signage and other information concerning beach conditions and open and closed areas; and
- Providing better maintenance of access routes and ramps.

In 1980, the North District Ranger prepared the ORV Plan North District Cape Hatteras National Seashore (NPS 1980). During development of this draft plan, the North District Ranger asked concerned individuals for comments and suggestions regarding ORV use at the Seashore. Based on these comments and suggestions, the plan included recommendations for improvements and a general description and project status of each soundside and oceanside access point from Bodie Island to Hatteras Inlet. The plan recommended that the general management plan consider additional parking needs on the soundside and oceanside and at comfort station locations. It also recommended that the general management plan consider impacts of traffic flow changes as a result of corridor and road closures (NPS 1980). The 1984 general management plan would address these concerns by incorporating additional parking lots and parking turnouts along NC-12 (NPS 1984); however, the 1980 draft ORV plan was not finalized or published as a special regulation, as required by Executive Orders 11644 and 11989 and 36 CFR 4.10.

The 1984 General Management Plan / Development Concept Plan / Environmental Assessment: Cape Hatteras National Seashore (NPS 1984) addressed direct and indirect threats to the Seashore, with ORV use cited as one such threat. The General Management Plan specified five visitor experience zones. ORV use was listed as an appropriate activity in three of these five zones: ocean/beach, interior dunes/maritime forests, and marsh/sound. The General Management Plan called for ORV use to be regulated by the 1978 draft interim ORV management plan (NPS 1978a) which was drafted after consideration of public comment to the 1978 draft plan (NPS 1978b). The General Management Plan called for additional planning and research on ORV use and for monitoring impacts of ORVs, but did not set forth an ORV management plan or special regulation, as required by Executive Orders 11644 and 11989 and 36 CFR 4.10.

ORV use was managed by the above planning documents during the 1980s and 1990s. On December 9, 1999, a petition for rulemaking was submitted to the NPS that requested a ban on the use of all-terrain vehicles (ATVs), dune buggies, sand buggies, and other four-wheel drive vehicles on all off-road areas in the national park system, which included the Seashore. This petition was followed-up by a second petition in 2004. The second petition, specific to the Seashore, was submitted on June 7, 2004, and requested Rulemaking Governing Off-Road Vehicle Use in the Cape Hatteras National Seashore. Petitioners claimed the Seashore's informal authorization of ORV use violated the ESA, executive orders and federal regulations regarding ORV use in the national parks, the *Organic Act*, the *General Authorities Act of 1970*, the Cape Hatteras National Seashore enabling legislation, and various NPS management policies. Both of these petitions are part of the reason for developing this ORV plan/EIS.

Following the submission of the two petitions, in 2004 the Seashore issued Superintendent's Order 7, ORV Management, to resolve ORV issues created by Hurricane Isabel, which flattened sand berms and exposed areas of the Seashore to ORV use that the berms once protected from such use (NPS 2004c). After reviewing the 1984 General Management Plan, the Superintendent decided that parts of the 1978 draft interim ORV management plan (permitting sections excluded) would be used as Seashore guidance pending development of a long-term ORV management plan and special regulation.

To provide guidance for the proper management of protected species and to comply with the ESA, while providing for use of the Seashore's recreational resources until an ORV plan/EIS and special regulation could be completed, the Seashore began development of the Interim Strategy in late 2004. The species addressed in the Interim Strategy are those specifically affected by recreational and ORV use within the Seashore that are listed either federally or by the state as threatened, endangered, or species of special concern, or are of special concern to the Seashore.

While the Interim Strategy was being prepared, Defenders of Wildlife issued a notice of intent (NOI) to sue the NPS for alleged violations of the ESA at the Seashore in May 2005. After this NOI was issued, the Seashore continued to develop the Interim Strategy, which was published for public comment in January 2006.

In December 2006, after the first season that NPS had operated under the Interim Strategy and after the USFWS had issued the Biological Opinion, Defenders of Wildlife issued another NOI to sue NPS and USFWS (collectively referred to as Federal Defendants), alleging that the Biological Opinion did not meet the requirements of the ESA and re-asserting the previously stated claims against NPS from the earlier NOI to sue. NPS issued a Finding of No Significant Impact (FONSI) on the Interim Strategy in July 2007 (NPS 2007a).

Alternative D, as modified in the Interim Strategy FONSI, was identified as the selected alternative. Alternative D outlines a multifaceted strategy (including a program of increased monitoring, recreational and ORV closures, education and enforcement) for minimizing impacts to wildlife, including threatened and endangered species and other protected species, from visitor uses including ORV use. The USFWS Raleigh Field Office prepared a Biological Opinion associated with the Interim Strategy in response to their review of the Cape Hatteras National Seashore's biological assessment (NPS 2006b, January 6, 2006), the Interim Strategy (NPS 2006a, January 18, 2006), and other sources of published and unpublished biological information. The Biological Opinion evaluated the proposed action of the Interim Strategy and its potential impact to protected species at the Seashore. The USFWS concluded that incidental take of protected species would occur from management actions under the Interim Strategy, but the level of anticipated take during the limited period the Interim Strategy would be in effect is not likely to result in jeopardy to the species or destruction or adverse modification of designated or proposed critical habitat (USFWS 2006a). In March 2007 and December 2007, the NPS requested reinitiation of consultation with the USFWS. These consultations concluded with the USFWS issuing amendments to its original Biological Opinion in April 2007 and March 2008, respectively. Both amendments addressed performance measures for piping plover and loggerhead, green, and leatherback sea turtles.

In October 2007, Defenders of Wildlife and the National Audubon Society, represented by the Southern Environmental Law Center (collectively referred to as Plaintiffs), filed a lawsuit claiming the Interim Strategy violated the ESA and other laws, failed to protect species at Cape Hatteras National Seashore, and failed to comply with the requirements of the ORV executive orders and NPS regulations on ORV use. In December 2007, Dare County, Hyde County, and the Cape Hatteras Access Preservation Alliance, a coalition of ORV/access and fishing groups, were granted Intervenor-Defendant status in the lawsuit.

In April 2008, the Plaintiffs, Federal Defendants, and Intervenor-Defendants jointly submitted to the court a consent decree that would be signed by a U.S. District Court Judge on April 30, 2008, to settle the

lawsuit. The consent decree, which is enforceable by the court, provides for specific species protection measures and requires the NPS to complete the ORV management plan/EIS and required special regulation by December 31, 2010, and April 1, 2011, respectively. Consent decree modifications of the Interim Strategy included changes in the size of buffers provided for various species at the Seashore, as well as added restrictions related to night driving.

## **SUMMARY OF SCIENTIFIC LITERATURE ON OFF-ROAD VEHICLE USE**

A literature review was prepared to support the development of an ORV management plan at Cape Hatteras National Seashore. The literature review (appendix A) provides a summary of available scientific information related to the potential effects of ORV use on natural and cultural resources similar to those found at the Seashore or in geographic locations with similar environmental conditions.

### **SCOPING PROCESS AND PUBLIC PARTICIPATION**

An NOI to prepare an Environmental Impact Statement was published in the Federal Register on December 11, 2006, to announce the beginning of the ORV planning process. To determine the scope of issues to be analyzed in depth in this plan/EIS, meetings were conducted in February and March of 2007 with Seashore staff, other parties associated with preparing this document, and members of the public. Additional public meetings were held in January 2008 and a public comment period was held in January – February 2008 to examine the range of alternatives and provide input on alternative elements. In response to public input and issues raised during the scoping process, the interdisciplinary planning team reworked the preliminary alternatives to those analyzed in this plan/EIS except for alternative F, which was developed after the negotiated rulemaking process concluded. A notice of availability for the draft plan/EIS was published in the *Federal Register* on March 12, 2010. Following the release of the draft plan/EIS, a 60-day public comment period was open between March 12, 2010, and May 11, 2010. Chapter 5 of this plan/EIS provides more details about agency and public scoping activities that were an integral part of the planning process for this plan/EIS.

### **NEGOTIATED RULEMAKING PROCESS**

The *Negotiated Rulemaking Act of 1990* (5 United States Code [USC] 561-570) establishes a statutory framework for agency use of negotiated rulemaking to reach a consensus with stakeholders on a proposed regulation. Concurrent with the *National Environmental Policy Act* (NEPA) process, the NPS used a negotiated rulemaking process in an effort to develop a proposed rule for long-term ORV management at the Seashore. Because negotiated rulemaking allows interested, affected parties more direct input into the development of the proposed regulation, the NPS had hoped that the negotiated rulemaking process would result in a rule that is sensitive to the needs and limitations of both the parties and the agency.

In December 2007, the Department of the Interior established a negotiated rulemaking advisory committee (Committee) to assist the NPS in the development of an ORV regulation for the Seashore. The Committee met 11 times from January 2007 through February 2009, and conducted numerous subcommittee and work group meetings and conference calls. The Committee discussed and explored options for the full spectrum of ORV management issues covered in this plan/EIS. As a result of these discussions, the NPS considered a variety of concepts and measures that either originated from Committee members or were discussed

---

*The NPS used a negotiated rulemaking process in an effort to develop a proposed rule for long-term ORV management at the Seashore.*

---

during Committee, subcommittee, or work group sessions. Although the Committee as a whole did not reach a consensus on a recommended alternative, in creating the alternatives in this plan/EIS, the NPS has made a management judgment as to which combination of concepts and measures would make an effective overall ORV management strategy.

## **ISSUES AND IMPACT TOPICS**

Issues associated with implementing an ORV management plan at Cape Hatteras National Seashore were initially identified by Seashore staff during internal scoping and were further refined through the public scoping and negotiated rulemaking processes. The following text discusses the issues that formed the basis for the impact topics discussed in chapters 3 and 4 of this plan/EIS.

### **FLOODPLAINS AND WETLANDS**

Although the entire ocean shoreline of the Seashore is classified as a marine or intertidal wetland (Cowardin et al. 1979), these areas are not measurably impacted by vehicle use due to the dynamic nature of the beach environment and the ability of the intertidal areas to “restore” themselves, since ruts from vehicle tires are filled in by wave action and moving sands. A study by Leatherman and Godfrey (1979) indicated that the intertidal ocean beach (sand beach area) is the most resistant to long-term vehicle impacts. While no definite conclusions were drawn from the study, they did indicate that natural changes to the beach appeared to overwhelm vehicle effects in this particular study. Given these studies, these types of wetlands were not analyzed in detail in this plan/EIS. However, vegetated wetlands along the soundside and interior of the islands are susceptible to direct damage from ORV use, and are discussed further under the “Wetlands” impact topic.

Estuarine wetlands are often denuded of vegetation when ORVs are driven and parked along the soundside shoreline. Also, many of the interior or interdunal roads are located near wetland areas that are often not noticeable to visitors. When standing water is present along these ORV routes, visitors often drive over adjacent vegetated areas in an attempt to avoid the standing water. This results in wider roads, new vehicle routes, and crushed or dead vegetation. Construction of new parking areas is also of concern for wetlands that may be located nearby.

Nearly all of the Seashore is located within the 100-year floodplain, with the exception of a small area at the Navy tower site on Bodie Island and larger areas around Buxton. In this plan/EIS, the issue of floodplains is considered under any alternative that includes development, such as constructing new parking lots or expanding existing parking lots, because these actions have the potential to impact the function and value of the floodplain. However, it is recognized that the barrier island floodplain systems function quite differently than inland floodplains, which primarily function by providing lowland areas for floodwater storage and conveyance. In contrast, floodplains at the Seashore are subject to coastal flooding caused by storm systems that can raise water levels substantially via storm surge.

### **WILDLIFE AND WILDLIFE HABITAT**

Cape Hatteras National Seashore provides important habitats and plays a vital role in the survival of many wildlife species. Whether for nesting, resting, foraging, or feeding, the Seashore provides for a diverse assemblage of birds. Rich, varied habitats and the Seashore’s location along the Atlantic Flyway attract birds. In 1999, the American Bird Conservancy designated Cape Hatteras National Seashore as a Globally Important Bird Area in recognition of the Seashore’s value in bird migration, breeding, and wintering (American Bird Conservancy 2005). This diverse ecosystem includes both prey species that sensitive species rely on for survival, and predators of sensitive species. ORV use along the Seashore can disrupt

habitat or cause a loss of habitat in high use areas. Habitat loss due to ORV use could also occur indirectly as a result of the noise and disturbance from this activity.

Invertebrates are impacted by ORV use. A recent study at the Seashore researched the ghost crab (*Ocypode quadrata*) as an indicator of ecosystem health, since it may show the impacts of ORVs and other recreational uses (Hobbs et al. 2008). The study considered the impacts of ORVs on ghost crab population densities and recovery rates in relation to ORV use and usage regulations. Data to determine the impacts of ORVs on crab populations were collected in several areas in the Seashore. Closures of the beaches to vehicles were initiated to study short-term effects and recovery rates. It was found that ORVs had a detrimental impact on ghost crab populations at the Seashore and that areas subject to vehicle use had significantly fewer ghost crab burrows than those areas without vehicles. As shown by Steiner and Leatherman (1981), ghost crabs can be killed or mortally injured by ORVs driving over them, or by altering their environment. This study concluded that high-energy weather events change the dynamics of the population, allowing more ghost crabs to inhabit the area, but ORVs reduce the ability for ghost crabs to inhabit the area (Hobbs et al. 2008).

### **FEDERALLY LISTED THREATENED OR ENDANGERED SPECIES**

ORV use at the Seashore could impact federally threatened or endangered species and their habitats on the Seashore's soundside and ocean beaches. Conflicts between listed species and recreational use (including ORV use) could create direct or indirect losses to a listed species. The Seashore is home to federally threatened or endangered species year-round. Increased year-round visitation results in a greater potential for conflicts between visitor use and listed species. The Seashore is used by both the endangered Great Lakes population of piping plover (considered threatened on wintering grounds, which include the Seashore) and the threatened Atlantic Coast population (for breeding and wintering, with breeding occurring at the Seashore). Seabeach amaranth, a federally listed threatened plant species, has been found in limited numbers at the Seashore in the recent past. However, no plants have been documented since 2005. According to the USFWS, seabeach amaranth has been eliminated from two-thirds of its historic range and ORVs are considered one of the more serious threats to its continued existence.

---

*The Seashore is home to federally threatened or endangered species year-round.*

---

Nesting sea turtles at the Seashore include the loggerhead, green, and leatherback turtles. Kemp's ridley and hawksbill turtles are known to occur only on the beaches of the Seashore through strandings. Threats to listed sea turtles, their nesting sites, and young include storm events, predation, artificial lighting, campfires, and recreational beach equipment; disturbance by pedestrians and pets; and direct and indirect impacts of ORVs. In May 2008, the red knot was identified by the USFWS as a candidate for the endangered or threatened species list. This species is a migrant and occasional winter resident at the Seashore.

Current and possible future management alternatives for ORV and other recreational uses would take into consideration the needs of federally listed threatened and endangered species in determining management measures.

### **STATE-LISTED AND SPECIAL STATUS SPECIES**

Habitat for state-listed and special status species, such as the American oystercatcher and several species of colonial waterbirds, may be vulnerable to disturbances caused by recreational uses, including ORV use. As of May 2008, the American oystercatcher, Wilson's plover, least tern, common tern, and black skimmer were listed by the North Carolina Wildlife Resources Commission (NCWRC) as species of

special concern (15A NCAC 10I.0105). The NCWRC also lists the gull-billed tern as a state-threatened species. The American oystercatcher is listed as a species of concern by the Southeastern Shorebird Conservation Plan, and both the American oystercatcher and the Wilson's plover are identified in the U.S. Shorebird Conservation Plan as "Species of High Concern" (Schulte et al. 2007; Brown et al. 2001). All these state-listed or special status species have had historically low reproductive rates. The lack of large undisturbed areas for successful breeding contributes to these low rates at the Seashore. Frequent human disturbance can cause the abandonment of nest sites as well as direct loss of eggs and chicks. In addition to these breeding species, the Seashore is also home to migratory species such as the red knot, that use habitat at the Seashore during the winter or during migration. The red knot is currently a candidate for ESA protection (74 FR 57804).

All of the bird species that are described under the "State-Listed and Species Status Species" sections of the plan/EIS are listed in 50 CFR § 10.13, which indicates species that are subject to the protections of the MBTA. These species are also designated as Birds of Conservation Concern (USFWS 2008b) and/or Migratory Nongame Birds of Management Concern in the United States (USFWS 1995) which qualifies them as species of concern according to Executive Order 13186, Responsibilities of Federal Agencies to Protect Migratory Birds. The Birds of Conservation Concern designation includes migratory and non-migratory species that are of concern due to population declines, naturally or human-caused small ranges or population sizes, threats to habitat, or other factors. The USFWS 1995 list of Migratory Nongame Birds of Management Concern in the United States lists species that are of concern because of (1) documented or apparent population declines, (2) small or restricted populations, or (3) dependence on restricted or vulnerable habitats. Therefore, the NPS is required to protect these species according to the provisions of both the executive order and the MBTA.

In April 2010, the NPS signed a Memorandum of Understanding (MOU) with the USFWS to strengthen coordination for migratory bird conservation. The MOU helps identify and implement strategies to complement and support existing efforts and facilitate new collaborative migratory bird conservation partnerships and comprehensive planning strategies for migratory birds under the MBTA. The Seashore has consulted with the USFWS on this plan/EIS, as provided for under the MOU.

## **SOUNDSCAPES**

Impacts related to soundscapes could occur wherever ORVs are allowed on the oceanside or the soundside. Vehicular noise has the potential to impact other recreational uses, such as bird watching or enjoying the solitude and natural soundscape of the Seashore. In addition to impacting soundscapes in relation to visitor enjoyment, vehicular noise could create unsuitable habitat for Seashore wildlife.

## **VISITOR USE AND EXPERIENCE**

ORV use at the Seashore is an integral component of the experience for some visitors and may be impacted by ORV management activities. Other Seashore visitors who are not using ORVs may be impacted by ORV use. Currently, the mix of recreational users at the Seashore includes a variety of users such as ORV users, day-users without ORVs, swimmers, anglers, bird watchers, water sports enthusiasts, and other users. Although some visitors want to use an ORV to access the Seashore, other visitors wish to engage in recreational activities on foot and away from the presence of motorized vehicles. Restricting ORVs from areas of the Seashore could enhance the recreational experience for some and diminish the experience for others. Visitor experience could be affected by conflicts between motorized and nonmotorized recreation users. A further component of visitor experience is providing for the safety of all visitors at the Seashore.

Other issues related to visitor use and experience include viewsheds, aesthetics, and night skies. While the sight of ORVs can destroy the viewshed and aesthetics for some visitors, they also change the viewshed by altering the natural landscape. Some visual signs of ORVs include tire ruts and markings and trash left behind. ORV use impedes or destroys coastal features like wave or wind ripples in the sand, tide wrack lines, overwash deposits, wind sorted sediments, dune formation, etc. As an example, the burrows of ghost crabs, the most common beach inhabitants, are nearly absent from beaches where ORVs are allowed. Installing posts around closure areas for protected species from ORVs could also impact the views and aesthetics of the area for those who want a natural view without evidence of man-made materials.

Headlights and other artificial lights associated with nighttime ORV use may affect visitors' opportunities to enjoy night skies at the Seashore. Conversely, lack of artificial lights may make it more difficult to see, posing hazards to ORV users and pedestrians. Issues related to night skies include night driving, headlights, campfires, and all other light uses associated with human activity after dusk. The Seashore is one of the few places on the Atlantic Coast where visitors can experience the magnificence of a dark night sky. The Seashore has been ranked, along with Cape Lookout National Seashore, as the 9<sup>th</sup> best place to view the night sky by the NPS Night Sky Program. ORV use at night has the potential to affect visitor experience of the "brilliance" of the night sky. In addition to visitors, animals are also impacted by lights at night. The stars, planets, and moon are visible during clear nights and influence many species of animals, such as birds that navigate by the stars or prey animals that reduce their activities during moonlit nights. Additionally, the phosphorescence of waves on dark nights helps sea turtle hatchlings orient to the ocean. Excessive artificial light has the potential to disorient turtle hatchlings and disrupt their crawl to the ocean. Pursuant to NPS Management Policy 4.10 (NPS 2006c), to prevent the loss of natural night skies, the NPS should minimize light that emanates from park facilities, and also seek the cooperation of park visitors, neighbors, and local government agencies to prevent or minimize the intrusion of artificial light into the night scene of the ecosystems of parks. Furthermore, the NPS will not use artificial lighting in areas such as sea turtle nesting locations where the presence of the artificial lighting could disrupt a park's dark-dependent natural resource components (NPS 2006c). Impacts of artificial light sources on animals will be discussed in chapters 3 and 4 under the threatened and endangered species, state-listed and sensitive species, and wildlife and wildlife habitat impact topics.

## **SOCIOECONOMICS**

Management or regulation of ORV use at the Seashore could impact the local economy by changing the demand for goods and services from ORV users in these communities. The eight villages located within the Seashore boundaries serve as access points to the Seashore for visitors, including ORV users. These villages receive economic benefit from the ORV users who take advantage of the goods and services these communities offer. The communities are concerned that if a permit system or other ORV restrictions are implemented that make it harder for ORV users to use the area, fewer tourists may come to the villages, resulting in impacts to the local economy.

Commercial fishermen currently have ORV access to areas that are closed to other ORV users because of safety reasons (i.e., narrow beach conditions), but they do not have access to areas closed for resource protection. On Ocracoke Island, two soundside access points have been identified for commercial use. Limits placed on ORV use at the Seashore may limit the activities of local commercial fishermen. Disrupting the ability of commercial fishermen to conduct business at the Seashore could negatively impact them.

## SEASHORE MANAGEMENT AND OPERATIONS

Accommodating recreational uses while protecting sensitive species requires a sufficient number of personnel and an adequate level of funding. Past anecdotal evidence suggested that the Seashore did not have enough personnel to properly enforce existing ORV management decisions. If operational requirements increase under the new ORV management plan, it would require an increased commitment of limited NPS resources (staff, money, time, and equipment).

## ISSUES CONSIDERED BUT DISMISSED FROM FURTHER ANALYSIS

The following issues were dismissed from further analysis.

**Geologic Resources:** ORV use may also impact the ocean beach at Cape Hatteras National Seashore by disturbing sand, compacting sand, creating ruts, and changing local topography. Studies have also shown that heavy ORV use could result in increased beach erosion (see the literature review in appendix A). However, the Seashore is part of a dynamic coastal barrier ecosystem, and visual effects of ORVs on ocean beaches can no longer be visible in a matter of hours due to daily tidal action, winds, rain, hurricanes, and other storm events. Although ORV use could impact geologic resources if ORVs are driven through dunes where there is no designated ramp, the use of ramps is strictly enforced and ORVs illegally cutting through dunes are rare occurrences at the Seashore, resulting in impacts that would be minor or less. ORV use can cause the collapse of beach escarpments and potentially affect sea turtle habitat. Ruts from ORV tires can also impact the behavior of piping plovers, and compaction of sand can impact invertebrate populations that are a food source for many of the shorebird species at the Seashore. However, these secondary impacts are addressed under the other impact topics in the plan/EIS including threatened or endangered species, state-listed and special status species, and wildlife and wildlife habitat. Therefore, the issue of geologic resources was not retained as an impact topic.

**Geohazards:** There are no known geohazards in the Seashore that would be affected by the implementation of an ORV management plan.

**Vegetation:** Numerous scientific studies have documented the impacts of ORV use on vegetation. However, because vegetation that exists near ORV use areas at the Seashore is almost exclusively wetland vegetation, impacts to vegetation were analyzed under the wetlands section in this plan/EIS. Potential impacts to the federally listed seabeach amaranth are addressed under the threatened and endangered species analysis in this document. Other vegetation that could be impacted from ORV use includes vegetation near the dunes, which functions to trap sand and facilitate natural dune building processes. All of the alternatives considered in this plan/EIS would include prohibitions from driving on the dunes, as well as mechanisms for establishing the ORV corridor so that any impacts to dune vegetation would be minimized. In addition, the plan/EIS would also include consultation and compliance under the *North Carolina Coastal Area Management Act (CAMA)*, which includes provisions for minimization of impacts to natural dunes. Given the alternative elements that minimize dune impacts, as well as the alternatives compliance with the CAMA, impacts to vegetation associated with dune processes would be expected to be negligible to minor and were not carried forward for detailed analysis in this document.

**Unique Ecosystems, Biosphere Reserves, World Heritage Sites:** There are no known biosphere reserves, World Heritage sites, or unique ecosystems listed in the Seashore; therefore, implementation of an ORV management plan would have no effect. The Seashore is classified as a Globally Important Bird Area and potential impacts to bird species are included for discussion in this document.

**Water Quality / Marine and Estuarine Resources:** ORV use has the potential to impact water quality at the Seashore due to fluids leaking from submerged vehicles or tire ruts altering natural drainage patterns. However, water quality impacts from submerged vehicles would not rise above the level of negligible as long as the vehicle was removed from the water in a timely fashion. Also, due to the ephemeral (temporary) nature of tire ruts in beach sand, they would not result in impacts to water quality. Therefore, this impact topic was dismissed from further analysis.

**Wildlife and Wildlife Habitat – Fish, Marine Mammals, and Mammals:** Essential fish habitat at the Seashore is located on the soundside in areas of submerged vegetation. As previously discussed, water quality impacts from ORV use would be negligible at most and would be associated primarily with vehicle use on the ocean side. Therefore, there would be no impacts to essential fish habitat and it is not addressed as an impact topic in this plan/EIS. Mammalian species at the Seashore include red fox (*Vulpes vulpes*), gray fox (*Urocyon cinereoargenteus*), coyote (*Canis latrans*), raccoon (*Procyon lotor*), Virginia opossum (*Didelphis virginiana*), eastern cottontail (*Sylvilagus floridanus*), deer mice (*Peromyscus* spp.), white-tailed deer (*Odocoileus virginianus*), muskrat (*Ondatra zibethica*), nutria (*Myocastor coypus*), otter (*Lutra* spp.), mink (*Neovison vison*), and others. Impacts to mammals from ORV use and management would be expected to be negligible as most of these species do not use ORV routes and areas as habitat. The alternatives discussed in this ORV management plan do not involve the removal of mammalian predators. Any impacts to the potential for an increase of mammalian predators due to increased human activity are discussed as an indirect impact to wildlife species in chapter 4 of this document. Impacts associated with predator control efforts will be discussed in the Seashore's forthcoming Predator Control Program for Protected Species Management / Environmental Assessment and as a cumulative impact in chapter 4 of this document. Although harassment of resting or stranded marine mammals on the beach could occur from various park users, including those using ORVs, the plan will include measures to educate all visitors about marine mammal protection, resulting in negligible to minor impacts. For the reasons mentioned above, impacts to terrestrial and marine mammals were dismissed from further analysis in this document.

**Air Quality:** Currently, Cape Hatteras National Seashore is located in an area classified by the U.S. Environmental Protection Agency (EPA) as being in attainment for all six criteria air pollutants. Activities associated with ORV use (such as driving or idling engines) result in the emission of criteria air pollutants; the pollutants of most concern for this project include nitrogen oxides (NO<sub>x</sub>), volatile organic compounds (VOCs), and particulate matter (PM). For this reason, the NPS completed a modeling analysis to quantify the magnitude of annual emissions associated with ORV activities at Cape Hatteras National Seashore, and utilized these results to determine whether additional air quality modeling was necessary to estimate downwind pollutant concentrations and associated impacts.

Emission factor estimates were computed using the current EPA recommended model for mobile source emissions, the EPA-developed Mobile Source Emissions Model (MOBILE6), and ORV data specific to the Seashore. The results of this analysis show that for the current average vehicle use patterns on the Seashore, emissions of VOCs, NO<sub>x</sub> and PM are all individually below 5 tons per year (TPY). Emissions for these pollutants associated with the upper bound estimates for ORV use patterns (i.e., the highest estimates of observed ORV use anticipated to occur park-wide on an annual basis under any of the alternatives) are just above 5 TPY, but all below 7 TPY. Given these low annual emission levels, daily pollutant concentrations resulting from ORV use are anticipated to be extremely low. Accordingly, it was determined that implementation of the ORV management plan would result in negligible air quality impacts, and air quality was dismissed from further analysis and discussion. The MOBILE6 modeling results and report are available on the plan/EIS project website at <http://parkplanning.nps.gov/CAHA>.

**Prime Farmlands:** There are no designated prime farmland soils in the Seashore.

**Streamflow Characteristics:** Actions related to ORV management would not have an effect on streamflow characteristics. The proposed actions would not occur in any area that would impact streamflow.

**Introduce or Promote Non-Native Species:** While the potential for vehicles to bring non-native species to the Seashore occurs, only a small number of non-native species can live in the salt and wind of the seashore environment. Additionally, ORVs are prohibited from driving on vegetation at the Seashore. Therefore, the potential for spreading plants from one area of the Seashore to another by driving on Seashore vegetation is also very low. *Phragmites (Phragmites australis)*, a non-native plant species, is present at the Seashore, but is not likely to be transported by ORVs because its primary method of colonization is by rhizomes (underground root extensions) and not by seeds, which are prone to spreading by vehicle tires (Wisconsin DNR 2007). Therefore, because of the low potential for ORVs to promote non-native species in such a dynamic, salty environment, this topic was not carried forward for analysis in this EIS.

**Archeological Resources:** Archeological resources are the remains of past human activity and records documenting the scientific analysis of these remains. Archeological features are typically buried but may extend above ground; they are commonly associated with prehistoric peoples but may be products of more contemporary society (NPS 1998). Cape Hatteras National Seashore is rich in prehistoric and historic culture. The Outer Banks are rich with history of humankind's attempt to survive at the edge of the sea, and with accounts of dangerous storms, shipwrecks, and valiant rescue efforts. As of fiscal year 2007, the NPS Archeological Sites Management Information System listed 28 archeological sites within the Seashore, ranging from a single projectile point (spear, dart, or arrow tip), to cemeteries, to the Cape Hatteras Lighthouse Complex, as well as shipwrecks. The condition of almost all of the extant resources was listed as good (NPS 2007d).

None of the archeological remains associated with structures, such as lighthouse complexes, are in immediate danger of damage from ORVs because those areas are not frequented by ORV users. Other archeological sites, such as cemeteries, are on the soundside of the island and are also not in areas frequented by ORV users. Therefore, the impact to these types of sites is considered negligible.

Thousands of shipwrecks have occurred along the coast. As a result of the ongoing research, the North Carolina Office of State Archaeology (OSA) Underwater Archaeology Branch catalog lists 63 historic shipwreck remains on beaches at the Seashore as of January 2008 (OSA 2008). At this time, none of the shipwrecks within the boundaries of the Seashore are listed in the National Register of Historic Places (National Register). One shipwreck, the Laura A. Barnes on Bodie Island Beach, was considered eligible for the National Register until its recent destruction by beach erosion during Hurricane Isabel (Stover pers. comm. 2009).

Shipwrecks on the beach are the resources of most concern because many of these shipwreck sites are ephemeral; in other words, they are uncovered and covered by storms, winds, and tides. This makes it difficult for NPS to manage them. If visible, the location of the resource is marked and protected, but many times the sand will move again before this is possible. Once resources are covered, or partially covered, it is possible that they could be run over or hit by ORV users who are unable to see them under the sand. In addition to unintentional impacts on the Seashore's cultural resources, some resources have been knowingly disturbed and even destroyed. ORV access also allows visitors to reach a shipwreck and take portions of the shipwreck that would normally be too large or heavy to remove if on foot (Stover pers. comm. 2009). During inventories of the condition of known shipwreck locations over the past seven years, NPS has found that an average of 25 to 30 of the 63 known shipwrecks are constantly being damaged by natural and human forces (Stover pers. comm. 2008).

The impact from unintentional ORV damage or intentional vandalism may be measurable or perceptible, but it is localized within a relatively small area of the site. Therefore, impacts on shipwrecks are considered minor. In general, impacts do not affect the character-defining features of any listed or eligible National Register archeological site at the Seashore. Therefore, this topic was not carried forward for further analysis.

**Cultural Landscapes:** The NPS defines cultural landscapes as settings that humans have created in the natural world. They reveal fundamental ties between people and the land. They are special places: expressions of human manipulation and adaptation of the land. Although only one Cultural Landscape Report has been prepared for the Cape Hatteras Light Station (NPS 2003a), there are five cultural landscapes within the Seashore's official database: Bodie Island Light Station, Little Kinnakeet Life Saving Station, Cape Hatteras Light Station, Hatteras Weather Bureau Station, and Ocracoke Light Station (NPS 1997; Stover pers. comm. 2008). None of these cultural landscapes is in the areas of routine ORV use under any of the proposed action alternatives, and none should be impacted by the implementation of an ORV management plan. In addition, because the oceanside ORV use areas under all alternatives are close to one mile from the Cape Hatteras Light Station, there should be no cultural landscape viewshed impacts from the base or the top of the lighthouse resulting from ORV use (Stover pers. comm. 2008).

**Historic Structures and Districts:** According to Director's Order 28, structures are defined as material assemblies that extend the limits of human capability. In plain language, this means a constructed work, usually immovable by nature or design, consciously created to serve some human activity. Examples are buildings, monuments, dams, roads, railroad tracks, canals, millraces, bridges, tunnels, locomotives, nautical vessels, stockades, forts and associated earthworks, Indian mounds, ruins, fences, and outdoor sculpture. The Seashore contains 36 historic structures, 20 of which are in good condition (NPS 2007b). Structures at the Seashore range from cemeteries to entire complexes. For example, three historic U.S. Life Saving Service stations still stand at Chicamacomico, Little Kinnakeet, and Bodie Island. The Hatteras Weather Bureau Station and Ocracoke Light Station are listed in the National Register. The Bodie Island Light Station, Bodie Island Lifesaving/Coast Guard Station, and Cape Hatteras Light Station are listed in the National Register as historic districts. In general, ORV use does not occur in the areas surrounding standing structures, because structures are located off the beach in the dunes or on the soundside of the Seashore. There are two tower concrete pad foundations (not standing structures). One is at Cape Point and the other is near Frisco Bath House. Only the foundation at Cape Point is in an area of ORV use but it is often buried and only becomes visible when the sands shift. Neither of these foundations is in danger of impact from ORVs.

**Ethnographic Resources:** An ethnographic study for the Seashore was completed in late 2005 (Impact Assessment, Inc. 2005). The study looked at the eight villages in the Seashore that reflect the nearly 300-year history and culture of the Outer Banks to support the Seashore in interpretation of its cultural resources, stewardship of ethnographic resources, and community relations with the villages. Archival/documentary research and ethnographic fieldwork was completed as part of the study to further socio-cultural understanding of the villages adjoining the Seashore. The villages contain a mix of populations that have evolved from the original British settlers, European seafarers, farmers, and other more recent migrants to the Outer Banks. No discrete, continuous ethnic groups or traditionally associated peoples (NPS *Management Policies 2006*, chapter 5) are documented for the Seashore; therefore, no ethnographic resources (NPS *Management Policies 2006*) would be impacted by the implementation of an ORV management plan.

In 2008, the Cape Hatteras Preservation Alliance submitted a request to the North Carolina Department of Cultural Resources (NCDCCR), State Historic Preservation Officer (SHPO) for Bodie Island Spit and adjoining beaches, Cape Point and adjoining beaches, Hatteras Inlet and adjoining beaches, and South

Point Ocracoke and adjoining beaches to be recognized as Traditional Cultural Properties (TCPs), eligible for inclusion in the National Register. The NCDCCR/SHPO responded to this request in a letter dated June 2, 2009, stating that a significance ascribed to a property in only the last 50 years cannot be considered traditional, and that the application focused on the past 50 years. The NCDCCR/SHPO also stated that in order to make the case that the sites qualify as TCPs worthy of preservation, documentation must be presented to substantiate the community's historically rooted beliefs, customs, and practices as they relate to recreational fishing and identify the "living community of people" who have established a pattern of land use reflected in the cultural traditions valued by its long-term residents. Further, documentation must show that the four sites are the specific places that played a significant role in the community's historically rooted beliefs, customs, and practices and that those beliefs, customs, and practices are integral to the community's cultural identity. The letter pointed out that most of the application's text appeared to focus on the past 50 years when recreational fishing at the sites has almost completely supplanted commercial fishing, a long-established practice (although not necessarily a traditional cultural practice as interpreted by the NPS) and the application provided no historical documentation to establish that recreational fishing practices of the past 50 years have a direct relationship and continuity with the traditional beliefs, customs, or practices associated with historical commercial fishing patterns on the Outer Banks. The NCDCCR/SHPO concluded that, based on the limited information in the application, there appears to be little if any justification that the properties qualify as TCPs.

The NPS concurs with this analysis, and has not found or been presented either with sufficient evidence that Outer Banks communities have cultural practices and beliefs associated with specific beaches or with a sufficient demonstration of an association with cultural practices and beliefs that are integral to the continuing cultural identity of any community. On October 21, 2009, the NPS further replied to this request stating that there is not sufficient evidence as to whether there are Outer Banks communities that have cultural practices and beliefs associated with specific beaches or sufficient information demonstrating an association between any community's cultural practices and beliefs that are integral to the continuing cultural identity of that community. Following an additional review, NPS determined the areas ineligible and provided its determination to the NCDCCR/SHPO, and the NCDCCR/SHPO offered no opinion. Because no TCPs were found to exist at the Seashore, this topic was not carried forward for analysis.

**Museum Collections:** Museum objects are manifestations and records of behavior and ideas that span the breadth of human experience and depth of natural history. The Seashore has collections of artifacts on display at the Cape Hatteras Lighthouse and at each visitor center. The official Seashore archives and artifact collections are housed at Fort Raleigh National Historic Site at Manteo. These various collections are not located on the ocean or soundside beaches and would not be impacted by implementation of an ORV management plan. Therefore this topic was not carried forward for further analysis.

**Indian Trust Resources.** The federal Indian trust responsibility is a legally enforceable fiduciary obligation on the part of the United States to protect tribal lands, assets, resources, and treaty rights. No Indian trust resources have been identified for Cape Hatteras National Seashore. Therefore, this impact topic is eliminated from further consideration.

**Sacred Sites.** Of the federally acknowledged tribes recognized pursuant to Public Law 103-454, 108 Statute 4791, the Tuscarora Nation is the only tribe affiliated with the Seashore. NPS is not aware of any historic properties that may be of religious and cultural significance to the Tuscarora Nation that would potentially be affected by the management alternatives described in the draft plan/EIS. The Seashore has consulted with the Tuscarora Nation about the ORV management draft plan/EIS, and the Tuscarora Nation has not informed the Seashore of sacred sites or other historic properties of religious or cultural significance to them which would be potentially affected. Therefore, the topic of sacred sites has been dismissed from further consideration.

**Environmental Justice:** On February 11, 1994, the President of the United States issued Executive Order 12898: Federal Actions to Address Environmental Justice in Minority and Low-Income Populations. The executive order is designed to focus the attention of federal agencies on the human health and environmental conditions in minority communities and low-income communities. Environmental justice analyses are performed to identify the disproportionate effects of high and adverse environmental or health impacts from proposed federal actions on minority or low-income populations, and to identify alternatives that could mitigate these impacts.

Data from the U.S. Department of Commerce 2000 Census of Population and Housing (U.S. Census Bureau 2008) identify minority populations as Black or African American; American Indian and Alaska Native; Asian; Native Hawaiian and other Pacific Islander; of some other race; of two or more races; and Hispanic or Latino. Poverty status, used in this plan/EIS to define low-income status, is reported as the number of persons with income below poverty level. The 2000 Census defines the poverty level as an annual income of \$8,794, or less, for an individual and an annual income of \$17,603, or less, for a family of four.

Dare and Hyde counties in North Carolina had a population of 35,793 in the year 2000, of whom 4,185 people (12%) were minorities and 3,271 (9%) were living below poverty level. People of Hispanic or Latino origin composed 787 (2%) of the total population; 2,854 (8%) were Black or African American; 107 (0.3%) were American Indian or Alaskan Native; 143 (0.4%) were Asian; 0 were Native Hawaiian or other Pacific Islander; 317 (0.8%) were of some other race; and 347 (0.9%) were of two or more races. It should be noted that persons of Hispanic or Latino origin may be of any race. The only village at the Seashore that is a Census Designated Place is Ocracoke Village. Ocracoke had a population of 769 in the year 2000, of whom 30 (3.9%) were minorities and 68 (9.3%) were living below poverty level.

The census block group containing the villages of Rodanthe, Waves, Salvo, and Avon had a population of 1,600 in the year 2000, of whom 55 people (3%) were minorities and approximately 11% were living below the poverty level. The census block group containing Hatteras Village had a population of 709 in the year 2000, of whom four people were minorities and approximately 3% were living below the poverty level. The census block group containing the villages of Buxton and Frisco had a population of 1,692 in the year 2000, of whom 24 were minorities and approximately 5% were living below the poverty level.

The data for the counties and the areas containing the villages indicate poverty rates that are lower than the national and state average of 12% in the year 2000. None of the minority populations in the area of the Seashore were above the state or national averages for those populations (U.S. Census Bureau 2008). Therefore, based on the definitions provided in the executive order for minority or low-income populations, there are no such populations that would be disproportionately impacted by the implementation of this plan/EIS.

**Energy Resources:** This topic involves assessing energy requirements and the potential for energy conservation associated with the various alternatives, but is most relevant to facility construction projects. The majority of ORV use at the Seashore involves gaining access to fishing areas, where vehicles are then turned off once the desired fishing spot is reached. Because vehicular access to the beach would be maintained under this plan/EIS at current or reduced levels, there would only be negligible impacts on energy resources, as public fuel consumption would not change to a large degree as a result of the implementation of this plan. However, due to differences in management intensity among the alternatives, there would be differences in energy (fuel) consumption from implementation of the ORV management plan. The Seashore would continue to operate under the wise energy use guidelines and requirements stated in the NPS 2006 Management Policies, Executive Order 13123 (Greening the Government Through Effective Energy Management), Executive Order 13031 (Federal Alternative Fueled Vehicle

Leadership), Executive Order 13149 (Greening the Government Through Federal Fleet and Transportation Efficiency), and the 1993 NPS Guiding Principles of Sustainable Design.

**Green House Gas Emissions and Climate Change:** There is strong evidence linking global climate change to human activities, especially greenhouse gas emissions associated with the burning of fossil fuels (IPCC 2007). Some of the activities associated with ORV management and use would result in fossil fuel consumption, for example, vehicular trips by Seashore personnel conducting monitoring and management activities such as erecting, moving, or removing species closures; marking ORV corridors; and law enforcement patrol and response in ORV areas would consume fossil fuels. Equipment used to construct and maintain ramps, interdunal roads, and parking areas would also consume fossil fuels. Additionally visitors driving ORVs on the Seashore beaches would result in fossil fuel consumption and release of greenhouse gas emissions. However, greenhouse gas emissions associated with the plan would be negligible in comparison to local, regional, and national greenhouse gas emissions. Therefore, the issue of the contribution of ORV management and use activities to climate change through greenhouse gas emissions was dismissed from further analysis.

**Urban Quality, Gateway Communities:** A gateway community is defined by the NPS *Management Policies 2006* as a community that exists in close proximity to a unit of the national park system whose residents and elected officials are often affected by the decisions made in the course of managing the park. Because of this, there are shared interests and concerns regarding decisions. Gateway communities usually offer food, lodging, and other services to park visitors. They also provide opportunities for employee housing and a convenient location to purchase goods and services essential to park administration. The communities within and adjacent to the Seashore would fall under this definition, and the issues and interests that would be impacted by this plan are addressed under the Socioeconomics impact topic.

**Paleontological Resources:** No paleontological resources are located within the Seashore that would be impacted by ORV use; therefore, paleontological resources would not be impacted by implementation of an ORV management plan.

**Health and Safety:** Large numbers of vehicles and pedestrians use many of the same Seashore beaches at the same time, increasing the potential for visitor use conflicts and safety issues. Health and safety issues related to ORV use are discussed under the Visitor Use topic.

**Topography and Soils:** Issues related to topography and soils include impacts to the sand and beach environment, which are discussed above under geologic resources. Since no other impacts would occur to soils or topographic conditions, these were not included as separate impact topics.

## **FEDERAL LAWS, POLICIES, REGULATIONS AND PLANS DIRECTLY RELATED TO OFF-ROAD VEHICLE MANAGEMENT**

### **Executive Order 11644: Use of Off-Road Vehicles on the Public Lands**

On February 8, 1972, President Richard Nixon issued Executive Order 11644 to “establish policies and provide for procedures that will ensure the use of ORVs on public lands will be controlled and directed so as to protect the resources of those lands, to promote the safety of all users of those lands, and to minimize conflicts among the various uses of those lands.”

The executive order directs agencies to develop and issue regulations and administrative instructions to designate the specific areas and trails on public lands on which ORV use may be permitted, and areas in which ORV use may not be permitted. The location of areas and trails shall:

- minimize damage to soil, watershed, vegetation, or other resources of the public lands;
- minimize harassment of wildlife or significant disruption of wildlife habitats;
- minimize conflicts between ORV use and other existing or proposed recreational uses of the same on neighboring public lands, and ensure the compatibility of such uses with existing conditions in populated areas, taking into account noise and other factors; and
- not be located in officially designated wilderness areas or primitive areas and shall be located in areas of the national park system, natural areas, or national wildlife refuges and game ranges only if the respective agency head determines that ORV use in such locations will not adversely affect their natural, aesthetic, or scenic values.

#### **Executive Order 11989: Off-Road Vehicles on Public Lands**

This executive order, issued on May 24, 1977, by President Jimmy Carter, directs agencies to immediately close off-road areas or trails when it is determined that the use of ORVs is causing or will cause considerable adverse effects on the soil, vegetation, wildlife, wildlife habitat or cultural or historic resources to the type of ORV causing such effects, until such time as determined that such adverse effects have been eliminated and measures have been implemented to prevent future recurrence. Also included in the executive order is the authority to adopt the policy that portions of the public lands under an agency's jurisdiction shall be closed to use by ORVs except those areas or trails that are suitable and specifically designated as open to such use.

#### **Code of Federal Regulations, Title 36, Section 4.10: Travel on Park Roads and Designated Routes**

This CFR section states, "operating a motor vehicle is prohibited except on park roads, in parking areas and on routes and areas designated for off-road motor vehicle use." Additionally, routes and areas designated for ORV use shall be promulgated as special regulations, with designations complying with Executive Order 11644 and 36 CFR 4.10. Routes and areas may be designated only in national recreation areas, national seashores, national lakeshores, and national preserves. As a result of the plan/EIS and special regulation, the Seashore will be in compliance with this regulation.

### **OTHER APPLICABLE FEDERAL LAWS, POLICIES, REGULATIONS AND PLANS**

This plan/EIS must conform to the following federal laws, policies, regulations, and plans described in this section. Although some of the following documents may not be directly related to ORV management, they are relevant to issues at the Seashore that may be indirectly influenced by or associated with ORV use.

#### **Code of Federal Regulations, Title 36**

Title 36, chapter 1, provides the regulations "for the proper use, management, government, and protection of persons, property, and natural and cultural resources within areas under the jurisdiction of the National Park Service." These regulations are utilized to fulfill the statutory purposes of the units of the national park system: to conserve scenery, natural and historical objects, and wildlife, and to provide for the

enjoyment of those resources in a manner that will leave them unimpaired for the enjoyment of future generations. Part 2 of these regulations establishes resource protection, public use, and recreation regulations applicable to public use of units of the national park system. Part 4 of these regulations establishes vehicle and traffic safety regulations applicable to areas within a park that are open to public traffic, which under this plan/EIS will include designated ORV routes.

### **Coastal Zone Management Act, 1966**

The *Coastal Zone Management Act* (CZMA) (16 USC 1451 et seq.) seeks to preserve and protect coastal resources. Through the CZMA, states are encouraged to develop coastal zone management programs (CZMPs) to allow economic growth that is compatible with the protection of natural resources, the reduction of coastal hazards, the improvement of water quality, and sensible coastal development. The CZMA provides financial and technical incentives for coastal states to manage their coastal zones in a manner consistent with CZMA standards and goals. CZMA Section 307 states, “Each Federal agency activity within or outside the coastal zone that affects any land or water use or natural resource of the coastal zone shall be carried out in a manner which is consistent to the maximum extent practicable with the enforceable policies of approved State management programs.”

---

*The Coastal Zone Management Act (CZMA) seeks to preserve and protect coastal resources.*

---

The CAMA (G.S. 113A) established the state’s cooperative program of coastal area management, including unified policies, criteria, standards, methods, and processes for dealing with land and water use decisions of more than local significance. This Act established the Coastal Resources Advisory Council and North Carolina Coastal Resources Commission, under the state’s Department of Environment and Natural Resources (NCDENR). The NCDENR Division of Coastal Management uses the rules and policies of the North Carolina Coastal Resources Commission to protect, conserve, and manage North Carolina’s coastal resources through an integrated program of planning, permitting, education, and research. These activities are carried out through the state’s responsibilities under the CAMA, the North Carolina Dredge and Fill Law (G.S. 113-229), and the federal CZMA in the 20 coastal counties. The CAMA program was federally approved in 1978 and is the state’s CZMP under the CZMA. Localities are responsible for planning while the state establishes areas of environmental concern. A project must obtain a CAMA permit if it:

- is in one of the 20 counties covered by the Act (including Dare and Hyde counties),
- is considered “development” under the Act,
- is in or affects an area of environmental concern (AEC), and
- does not qualify for an exemption.

As a part of this program, the Coastal Resources Commission designated “areas of environmental concern” in the 20 coastal counties and set rules for managing development in these areas. An AEC is an area of natural importance that may be easily destroyed by erosion or flooding or that may have environmental, social, economic, or aesthetic values that make it valuable to North Carolina. At least 90 days prior to taking action, NPS would provide a consistency determination stating how the plan/EIS is, to the maximum extent practicable, consistent with the enforceable policies of the CAMA.

### **Endangered Species Act of 1973, as Amended**

The 1973 ESA provides for the conservation of ecosystems upon which threatened and endangered species of fish, wildlife, and plants depend. Section 7 of this Act requires all federal agencies to consult

with the Secretary of the Interior on all projects and proposals with the potential to impact federally endangered or threatened plants and animals. It also requires federal agencies to use their authorities in furtherance of the purposes of the ESA by carrying out programs for the conservation of endangered and threatened species. Federal agencies are also responsible for ensuring that any action authorized, funded, or carried out by the agency is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of designated critical habitat. Section 9 of the Act makes it unlawful for a person to “take” a listed animal without a permit. The term “take” is defined in the Act as “to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect or attempt to engage in any such conduct.” Through regulations, the term “harm” is defined as “an act which actually kills or injures wildlife. Such an Act may include significant habitat modification or degradation where it actually kills or injures wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering.” Listed plants are not protected from take, although it is illegal to collect or maliciously harm them on federal land. The Act also imposes civil and criminal penalties for violations of any provisions of the Act.

### **Critical Habitat Designation for Piping Plovers**

Under the authority of Section 4 of the ESA, the USFWS must, to the maximum extent prudent and determinable, designate critical habitat for protected species. “Critical habitat” refers to (1) specific geographic areas occupied by the species at the time it is listed as threatened or endangered that contain features essential for the conservation of a threatened or endangered the species and that may require special management or protection; and (2) areas outside the areas occupied by the species at the time it is listed that are nonetheless determined to be essential to the conservation of the species. On October 21, 2008 (73 FR 62816), the USFWS published a revised designation for the following areas as critical habitat for the wintering population of the piping plover in the Seashore: (1) Unit NC-1, Oregon Inlet; (2) Unit NC-2, Cape Hatteras Point; (3) Unit NC-4, Hatteras Inlet; and (4) Unit NC-5, Ocracoke Island. Unit NC-1 is approximately 5 miles long, and consists of about 485 acres of sandy beach and inlet spit habitat on Bodie Island and Pea Island. Unit NC-2 comprises 646 acres and extends south approximately 2.8 miles from the ocean groin near the old location of the Cape Hatteras Lighthouse to the point of Cape Hatteras, and then extends west 4.7 miles along South Beach to the edge of ramp 49 near the Frisco campground. Unit NC-4 is approximately 5 miles long and consists of 410 acres of sandy beach and inlet spit habitat on the western end of Hatteras Island and the eastern end of Ocracoke Island. Unit NC-5 consists of 502 acres on the western portion of Ocracoke Island beginning at the beach access point at the edge of ramp 72 (South Point Road), extending west approximately 2.1 miles to Ocracoke Inlet, and then back east on the Pamlico Sound side. On February 6, 2009, Cape Hatteras Access Preservation Alliance and Dare and Hyde Counties, North Carolina filed a legal challenge to the revised designation. On August 18, 2010, a U.S. District Court granted the government’s motion for summary judgment and dismissed the case with prejudice, and the critical habitat designation for these four units remains in effect. Under Section 7(a)(2) of the ESA, if a federal action may affect a listed species or its critical habitat, the responsible federal agency must enter into consultation with the USFWS to ensure that the affected critical habitat would remain functional to serve its intended conservation role for the species.

### **Antideficiency Act**

The *Antideficiency Act* is a series of statutes (originating from 16 Stat. 251 in 1870) that prohibit federal managers from making or authorizing expenditures in excess of the amount available to them from appropriations or other funds, unless authorized by law. Based on this, the plan/EIS created must be able to be implemented through expected funding sources.

### **Marine Mammal Protection Act, 1972**

The *Marine Mammal Protection Act* (MMPA) prohibits, with certain exceptions, the taking of marine mammals in U.S. waters and by U.S. citizens on the high seas, and the importation of marine mammals and marine mammal products into the United States. The MMPA defines “take” as “to harass, hunt, capture, or kill, or attempt to harass, hunt, capture, or kill any marine mammal.” It defines harassment as “any act of pursuit, torment, or annoyance which has the potential to injure a marine mammal or marine mammal stock in the wild; or has the potential to disturb a marine mammal or marine mammal stock in the wild by causing disruption of behavioral patterns, including but not limited to, migration, breathing, nursing, breeding, feeding, or sheltering.” The MMPA recognizes that some marine mammal species or stocks may be in danger of extinction or depletion as a result of human activities, and that these species or stocks must not be permitted to be depleted. The MMPA, as amended in 1994, provides for certain exceptions to the take prohibitions, such as Alaska Native subsistence and permits and authorizations for scientific research; a program to authorize and control the taking of marine mammals incidental to commercial fishing operations; preparation of stock assessments for all marine mammal stocks in waters under U.S. jurisdiction; and studies of pinniped-fishery interactions.

This Act is relevant to this plan/EIS in two ways. ORVs are often used to respond to stranded marine mammals, and can be essential for quick and humane response. These actions are coordinated by the National Oceanic and Atmospheric Administration (NOAA) and/or the Seashore with government vehicles, and are considered beneficial for the protection and management of marine mammals on the Seashore. ORVs also have the potential to impact resting or stranded marine mammals due to the fact that ORVs facilitate access to and increase visitor presence in relatively remote sections of the beach, which could bring people and vehicles into direct, short-term contact with resting or stranded marine mammals. This increases the potential for resting or stranded marine mammals to be disturbed or harassed. For example, harassment of resting seals has been documented numerous times on the Seashore, and ORVs would most likely continue to contribute to this as the area’s winter seal population continues to increase.

### **Migratory Bird Treaty Act of 1918 and Executive Order 13186: Responsibilities of Federal Agencies to Protect Migratory Birds**

Migratory birds are of great ecological and economic value to this country and to other countries. They contribute to biological diversity and bring tremendous enjoyment to millions of people who study, watch, feed, or hunt these birds throughout the United States and other countries. The United States has recognized the critical importance of this shared resource by ratifying international, bilateral conventions for the conservation of migratory birds. These migratory bird conventions impose substantive obligations on the United States for the conservation of migratory birds and their habitats, and through the MBTA, the United States has implemented these migratory bird conventions with respect to the United States. Executive Order 13186 directs executive departments and agencies to take certain actions to further implement the MBTA. The MBTA implements various treaties and conventions between the United States and Canada, Japan, Mexico, and the former Soviet Union for the protection of migratory birds. Under this Act, it is prohibited, unless permitted by regulations, to “pursue, hunt, take, capture, kill, attempt to take, capture or kill, possess, offer for sale, sell, offer to purchase, purchase, deliver for shipment, ship, cause to be shipped, deliver for transportation, transport, cause to be transported, carry, or cause to be carried by any means whatever, receive for shipment, transportation or carriage, or export, at any time, or in any manner, any migratory bird, included in the terms of this Convention...for the protection of migratory birds...or any part, nest, or egg of any such bird” (16 USC 703). Subject to limitations in the Act, the Secretary of the Interior may adopt regulations determining the extent to which, if at all, hunting, taking, capturing, killing, possessing, selling, purchasing, shipping, transporting or exporting of any migratory bird, part, nest or egg will be allowed, having regard for temperature zones, distribution, abundance, economic value, breeding habits and migratory flight patterns.

### **National Environmental Policy Act, 1969, as Amended**

NEPA is implemented through regulations of the Council on Environmental Quality (CEQ) (40 CFR 1500–1508). The NPS has in turn adopted procedures to comply with NEPA and the CEQ regulations, as found in Director’s Order 12: Conservation Planning, Environmental Impact Analysis, and Decision Making, and its accompanying handbook (NPS 2001a). Section 102 (2)(C) of NEPA requires that an EIS be prepared for proposed major federal actions that may significantly affect the quality of the human environment.

---

*Section 102(2) (C) of  
the National  
Environmental Policy  
Act requires that an  
EIS be prepared for  
proposed major  
federal actions that  
may significantly  
affect the quality of  
the human  
environment.*

---

### **National Historic Preservation Act of 1966, as Amended**

Section 106 of this Act requires federal agencies to consider the effects of their undertakings on properties listed or potentially eligible for listing on the National Register of Historic Places. All actions affecting the Seashore’s historic, archaeological, and cultural resources must comply with this legislation. For this plan/EIS, compliance with Section 106 is being combined with NEPA compliance.

### **National Parks Omnibus Management Act of 1998**

Both the *National Parks Omnibus Management Act of 1998* (NPOMA) (16 USC 5901 et seq.) and NEPA are fundamental to NPS park management decisions. Both acts provide direction for articulating and connecting the ultimate resource management decision to the analysis of impacts, using appropriate technical and scientific information. Both also recognize that such data may not be readily available and provide options for resource impact analysis in this case.

### **NPS Organic Act, as Amended**

By enacting the *Organic Act of 1916*, Congress directed the U.S. Department of the Interior and NPS to manage units of the national park system “to conserve the scenery and the natural and historic objects and the wild life therein and to provide for the enjoyment of the same in such manner and by such means as will leave them unimpaired for the enjoyment of future generations” (16 USC 1). The 1978 *Redwood Amendment* reiterates this mandate by stating that the NPS must conduct its actions in a manner that will ensure no “derogation of the values and purposes for which these various areas have been established, except as may have been or shall be directly and specifically provided by Congress” (16 USC 1 a-1). Congress intended the language of the *Redwood Amendment* to reiterate the provisions of the *Organic Act*, not to create a substantively different management standard. The House Committee report described the *Redwood Amendment* as a “declaration by Congress” that the promotion and regulation of the national park system is to be consistent with the *Organic Act*. The Senate Committee report stated that under the *Redwood Amendment*, “The Secretary has an absolute duty, which is not to be compromised, to fulfill the mandate of the 1916 Act to take whatever actions and seek whatever relief as will safeguard the units of the national park system.” Although the *Organic Act* and the *Redwood Amendment* use different wording (“unimpaired” and “derogation”) to describe what the NPS must avoid, both acts define a single standard for the management of the national park system—not two different standards. For simplicity, NPS *Management Policies 2006* uses “impairment,” not both statutory phrases, to refer to that single standard.

Despite these mandates, the *Organic Act* and its amendments afford the NPS latitude when making resource decisions to allow appropriate visitor use while preserving resources. By these acts Congress “empowered [the NPS] with the authority to determine what uses of park resources are proper and what

proportion of the park's resources are available for each use" (*Bicycle Trails Council of Marin v. Babbitt*, 82 F.3d 1445, 1453 [9th Cir. 1996]).

Courts consistently interpret the *Organic Act* and its amendments to elevate resource conservation above visitor recreation. *Michigan United Conservation Clubs v. Lujan*, 949 F.2d 202, 206 (6<sup>th</sup> Cir. 1991) states: "Congress placed specific emphasis on conservation." The court in *National Rifle Association of America v. Potter*, says "in the *Organic Act* Congress speaks of but a single purpose, namely, conservation." The *NPS Management Policies 2006* also recognize that resource conservation takes precedence over visitor recreation. The policy dictates: "when there is a conflict between conserving resources and values and providing for enjoyment of them, conservation is to be predominant" (NPS 2006c, sec. 1.4.3, 10). This policy has been further reiterated in a recent court ruling on the Yellowstone Winter Use Plan/EIS (*National Parks Conservation Association v. National Park Service* – No. 07-2112) that states,

The *Organic Act* charges the NPS with the duty to provide for the enjoyment: of the parks' resources and values in "such manner and by such means as will leave them unimpaired for the enjoyment of future generations" 16 U.S.C. Section 1. This is not blanket permission to have fun in the parks in any way the NPS sees fit. As Plaintiffs articulated at the hearing, the "enjoyment" referenced in the *Organic Act* is not enjoyment for its own sake, or even enjoyment of the parks generally, but rather the enjoyment of "the scenery and natural and historic objects and the wild life" in the parks in a manner that will allow future generations to enjoy them as well.

Because conservation remains predominant, the NPS seeks to avoid or to minimize adverse impacts on park resources and values. Yet, the NPS has discretion to allow negative impacts when necessary (NPS 2006c, sec. 1.4.3, 10). While some actions and activities cause impacts, the NPS cannot allow an adverse impact that constitutes resource impairment (NPS 2006c, sec. 1.4.3, 10). Specifically, *NPS Management Policies 2006*, section 1.4.3.1 states: "In the administration of authorized uses, park managers have the discretionary authority to allow and manage the use, provided that the use will not cause impairment or unacceptable impacts." The *Organic Act* prohibits actions that permanently impair park resources unless a law directly and specifically allows for the action (16 USC 1a-1). An action constitutes "an impairment" when its impacts "harm the integrity of park resources or values, including the opportunities that otherwise would be present for the enjoyment of those resources or values" (NPS 2006c, sec. 1.4.5, 11). To determine impairment, the NPS must evaluate "the particular resources and values that would be affected; the severity, duration, and timing of the impact; the direct and indirect effects of the impact; and the cumulative effects of the impact in question and other impacts" (NPS 2006c, sec. 1.4.5, 11).

Park managers must also not allow uses that would cause unacceptable impacts (NPS 2006c, sec. 1.4.7, 12) These are impacts that fall short of impairment, but are still not acceptable within a particular park's environment. For the purposes of these policies, unacceptable impacts are impacts that, individually or cumulatively, would

- be inconsistent with a park's purposes or values, or
- impede the attainment of a park's desired future conditions for natural and cultural resources as identified through the park's planning process, or
- create an unsafe or unhealthful environment for visitors or employees, or
- diminish opportunities for current or future generations to enjoy, learn about, or be inspired by park resources or values, or

- unreasonably interfere with
  - park programs or activities, or
  - an appropriate use, or
  - the atmosphere of peace and tranquility, or the natural soundscape maintained in wilderness and natural, historic, or commemorative locations within the park, or
  - NPS concessioner or contractor operations or services.

Because park units vary based on their enabling legislation, natural resources, cultural resources, and missions, management activities appropriate for each unit, and for areas in each unit, vary as well. An action appropriate in one unit could impair or cause unacceptable impacts to resources in another unit. Since publication of the DEIS in March 2010, the NPS has issued Interim Guidance for Impairment Determinations in NPS NEPA documents (NPS 2010h). Consistent with the Interim Guidance, a draft plan/EIS written impairment determination only for the preferred alternative is included in appendix E of this final plan/EIS, and the impact analysis for the no-action alternative A in the final/plan EIS discusses the potential of alternative A to result in impairment to sea turtles, common tern, gull-billed tern, and black skimmer.

#### **Executive Order 11990: Protection of Wetlands**

This executive order directs federal agencies to avoid, to the extent possible, the long-term and short-term adverse impacts associated with the destruction or modification of wetlands, and to avoid direct or indirect support of new construction in wetlands wherever there is a practicable alternative.

#### **Executive Order 11988: Floodplain Management**

This executive order directs federal agencies to avoid, to the extent possible, the long-term and short-term adverse impacts associated with the occupancy and modification of floodplains, and to avoid direct or indirect support of floodplain development wherever there is a practicable alternative.

#### **NPS Management Policies 2006**

NPS *Management Policies 2006* address management of ORVs in section 8.2.3.1, Off-Road Vehicle Use. This section states (NPS 2006c):

Off-road motor vehicle use in national park units is governed by Executive Order 11644 (*Use of Off-Road Vehicles on the Public Lands*, as amended by Executive Order 11989), which defines off-road vehicles as “any motorized vehicle designed for or capable of cross-country travel on or immediately over, land, water, sand, snow, ice, marsh, swampland, or other natural terrain” (except any registered motorboat or any vehicle used for emergency purposes). Unless otherwise provided by statute, any time there is a proposal to allow a motor vehicle meeting this description to be used in a park, the provisions of the executive order must be applied.

In accordance with 36 CFR 4.10(b), routes and areas may be designated only in national recreation areas, national seashores, national lakeshores, and national preserves, and only by special regulation. In accordance with the executive order, they may be allowed only in locations where there will be no adverse impacts on the area’s natural, cultural, scenic, and esthetic values, and in consideration of other existing or proposed recreational uses.

The criteria for new uses, appropriate uses, and unacceptable impacts listed in sections 8.1 and 8.2 must also be applied to determine whether off-road vehicle use may be allowed. As required by the executive order and the *Organic Act*, superintendents must immediately close a designated off-road vehicle route whenever the use is causing, or will cause, unacceptable impacts on the soil, vegetation, wildlife, wildlife habitat, or cultural and historic resources.

NPS administrative off-road motor vehicle use will be limited to what is necessary to manage the public use of designated off-road vehicle routes and areas; to conduct emergency operations; and to accomplish essential maintenance, construction, and resource protection activities that cannot be accomplished reasonably by other means.

Management policies relating to resource protection also were considered in developing this plan/EIS. For example, NPS *Management Policies 2006* instructs park units to maintain, as parts of the natural ecosystems of parks, all plants and animals native to park ecosystems, in part by minimizing human impacts on native plants, animals, populations, communities, and ecosystems, and the processes that sustain them (NPS 2006c, sec. 4.4.1).

NPS *Management Policies 2006* directs park units to determine all management actions for the protection and perpetuation of federally, state, or locally listed species through the park management planning process, and to include consultation with lead federal and state agencies as appropriate. Section 4.4.2.3, Management of Threatened or Endangered Plants and Animals, specifically states:

The NPS will survey for, protect, and strive to recover all species native to national park system units that are listed under the *Endangered Species Act*. The NPS will fully meet its obligations under the *Organic Act* and the *Endangered Species Act* to both proactively conserve listed species and prevent detrimental effects on these species. To meet these obligations, the NPS will:

- Cooperate with both the USFWS and the National Marine Fisheries Service (NMFS) to ensure that NPS actions comply with both the written requirements and the spirit of the *Endangered Species Act*. This cooperation should include the full range of activities associated with the *Endangered Species Act*, including consultation, conferencing, informal discussions, and securing of all necessary scientific and/or recovery permits.
- Undertake active management programs to inventory, monitor, restore, and maintain listed species' habitats; control detrimental non-native species; control detrimental visitor access; and re-establish extirpated populations as necessary to maintain the species and the habitats upon which they depend.
- Manage designated critical habitat, essential habitat, and recovery areas to maintain and enhance their value for the recovery of threatened and endangered species.
- Cooperate with other agencies to ensure that the delineation of critical habitat, essential habitat, and/or recovery areas on park-managed lands provides needed conservation benefits to the total recovery efforts being conducted by all the participating agencies.
- Participate in the recovery planning process, including the provision of members on recovery teams and recovery implementation teams where appropriate.

- Cooperate with other agencies, states, and private entities to promote candidate conservation agreements aimed at precluding the need to list species.
- Conduct actions and allocate funding to address endangered, threatened, proposed, and candidate species.

Section 4.4.2.3 of the *NPS Management Policies 2006* also states, “NPS will inventory, monitor, and manage state and locally listed species in a manner similar to its treatment of federally listed species, to the greatest extent possible. In addition, the Service will inventory other native species that are of special management concern to parks (such as rare, declining, sensitive, or unique species and their habitats) and will manage them to maintain their natural distribution and abundance” (NPS 2006c, sec. 4.4.2.3).

### **Cape Hatteras National Seashore Enabling Legislation, 1937**

This legislation was an act of Congress that provided for the authorization of the Cape Hatteras National Seashore. Section 3 of the Seashore’s enabling legislation (the Act) states, “the administration, protection, and development of the aforesaid national seashore shall be exercised under the direction of the Secretary of the Interior by the National Park Service, subject to the provisions of the Act of August 25, 1916 (39 Stat. 535),” which is more commonly known as the *Organic Act*. Section 3 continues by stating, “that the legal residents of villages...shall have a right to earn a livelihood by fishing within the boundaries to be designated by the Secretary of the Interior, subject to such rules and regulations as the said Secretary may deem necessary in order to protect the area for recreational use as provided for in this Act.” Section 4 of this legislation states, “Except for certain portions of the area, deemed to be especially adaptable for recreational uses, particularly swimming, boating, sailing, fishing, and other recreational activities of similar nature, which shall be developed for such uses as needed, the said areas shall be permanently reserved as a primitive wilderness and no development of the project or plan for the convenience of visitors shall be undertaken which would be incompatible with the preservation of the unique flora and fauna or the physiographic conditions now prevailing in this area.”

### **Code of Federal Regulations Title 36, Section 7.58, Commercial Fishing**

Section 7.58 contains the regulations governing commercial fishing at the Seashore. This section includes details on the requirements for commercial fishing permits, sport fishing zones, beach sanitation, and conservation of aquatic life.

### **Code of Federal Regulations Title 36, Section 2.2, Wildlife Protection**

Section 2.2 address the protection of wildlife at the Seashore and prohibits the following: the taking of wildlife, except by authorized hunting and trapping activities conducted in accordance with paragraph (b) of Section 2.2; the feeding, touching, teasing, frightening or intentional disturbing of wildlife nesting, breeding or other activities; and possessing unlawfully taken wildlife or portions thereof.

### **NPS Director’s Order 12: Conservation Planning, Environmental Impact Analysis, and Decision Making and Handbook**

Director’s Order 12 and its accompanying handbook (NPS 2001a) lay the groundwork for how the NPS complies with NEPA. Director’s Order 12 and handbook set forth a planning process for incorporating scientific and technical information and establishing a solid administrative record for NPS projects.

Director’s Order 12 requires that impacts to park resources be analyzed in terms of their context, duration, and intensity. It is crucial for the public and decision makers to understand the implications of those

impacts in the short and long term, cumulatively, and within context, based on an understanding and interpretation by resource professionals and specialists.

### **NPS Director’s Order 28: Cultural Resource Management**

Director’s Order 28 sets forth the guidelines for management of cultural resources, including cultural landscapes, archeological resources, historic and prehistoric structures, museum objects, and ethnographic resources. This order calls for the NPS to protect and manage cultural resources in its custody through effective research, planning, and stewardship in accordance with the policies and principles contained in the *NPS Management Policies 2006*.

### **NPS Director’s Order 77: Natural Resource Protection**

Director’s Order 77 addresses natural resource protection, with specific guidance provided in Reference Manual 77: Natural Resource Management. Natural Resource Management Reference Manual 77 offers comprehensive guidance to NPS employees responsible for managing, conserving, and protecting the natural resources found in National Park System units. The Reference Manual serves as the primary guidance on natural resource management in units of the National Park System. Reference Manual chapters that are particularly relevant to this plan/EIS include endangered, threatened, and rare species management; geologic resources management; native animal management; shoreline management; vegetation management; special use permitting; wetland protection (Director’s Order 77-1); and floodplain management (Director’s Order 77-2).

## **RELATIONSHIP TO OTHER CAPE HATTERAS NATIONAL SEASHORE PLANNING DOCUMENTS, POLICIES AND ACTIONS**

The following plans, policies, and actions occurring at the Seashore were considered during the development of this plan/EIS.

### **Past Off-Road Vehicle Planning Efforts**

As described under “Summary of Off-Road Vehicle Use and Management at Cape Hatteras National Seashore” earlier in this chapter, the Seashore has engaged in various ORV management activities since it was established. All of these past planning efforts were taken into consideration during the development of this plan/EIS.

### **General Management Plan**

The 1984 General Management Plan / Development Concept Plan / Environmental Assessment for Cape Hatteras National Seashore was developed to guide the preservation, use, development, and operation of the Seashore for a 5- to 10-year period. The relationship of the General Management Plan to ORV use at the Seashore is described in greater detail under “Summary of Off-Road Vehicle Use and Management at Cape Hatteras National Seashore” earlier in this chapter.

### **Resource Management Plan**

The 1997 resource management plan states that the use of ORVs at the Seashore is a matter of growing controversy, and impacts from these vehicles on natural resources and pedestrian visitors are informally monitored on a continual basis. The plan noted, but did not cite, a study examining the effects of human-related disturbances, including vehicles, on migrating shorebirds and waterbirds, and stated that more detailed studies would be required to establish effective ORV management.

### **Visitor Services Project Report**

The visitor services project report, or the Outer Banks Group Parks Visitor Study Cape Hatteras National Seashore Visitors, resulted from a visitor study conducted at the Seashore July 12 through 18, 2002. The study found that the most popular activities for current and past visitors were sunbathing/swimming and visiting historic sites. The three most important reasons for visiting the Seashore were the lighthouses, swimming, and uncrowded / solitude / low population. Also, when asked about crowding, 27% of visitors said they felt “crowded” to “extremely crowded” while 43% of visitors felt “somewhat crowded.” Many visitor groups (49%) felt that crowding “detracted from their park experience” (NPS 2002a).

### **Long-Range Interpretation Plan**

A long-range interpretation plan for the Seashore was completed in September 2007. The Long-Range Interpretation Plan recommends actions to be taken over the next five to seven years to improve the Seashore’s personal services program and interpretive media, and provides an achievable implementation strategy (NPS 2007d). Because the plan addresses exhibits, interpretive information, outreach, and education, it was considered in the development of this plan/EIS.

### **RELATIONSHIP TO OTHER FEDERAL PLANNING DOCUMENTS AND ACTIONS**

In addition to the laws and policies above, other federal planning documents exist that directly or indirectly relate to ORV use at the Seashore, and were taken into consideration during the development of this plan/EIS.

### **Piping Plover Atlantic Coast Population Recovery Plan**

ORV management activities described in this plan/EIS considered the 1996 USFWS Piping Plover Atlantic Coast Population Recovery Plan (USFWS 1996a). This population of piping plovers was listed as threatened in 1986 and has increased from approximately 800 pairs to almost 1,350 pairs in 1995. However, pressure on Atlantic Coast beach habitat from development and human disturbance is pervasive and unrelenting, and the species is sparsely distributed. Increased human activity in Atlantic Coast parks, which includes increased ORV use, is cited as one of the many reasons the piping plover was listed.

### **Recovery Plan for the Great Lakes Piping Plover**

This plan/EIS considered the USFWS Recovery Plan for the Great Lakes Piping Plover. The Great Lakes population, members of which are believed to overwinter at the Seashore, was listed as endangered under provisions of the ESA on January 10, 1986. The Great Lakes population had declined from a historic size of several hundred breeding pairs to 17 at the time of listing. From 1986 through 2002, the population fluctuated between 12 and 51 breeding pairs, with breeding areas remaining largely confined to Michigan. The restricted breeding range of this population creates a gap in the distribution of piping plovers across North America, with the Great Lakes population isolated from the two other breeding populations (Atlantic and Northern Great Plains) (USFWS 2003).

### **Atlantic Green, Hawksbill, Leatherback, Kemp’s Ridley, and Loggerhead Turtle Recovery Plans**

The USFWS and the NMFS recovery plans for the U.S. population of Atlantic green, hawksbill, leatherback, Kemp’s ridley, and loggerhead sea turtles were considered when developing this plan/EIS. Each of these species is federally listed and the Seashore considered the individual recovery plans (NMFS and USFWS 1991, 1992a, 1992b, 1993, 2008).

### **Marine Mammal Recovery Efforts by the National Marine Fisheries Service**

This plan/EIS considered the Marine Mammal Recovery Efforts of the NMFS. The NMFS Office of Protected Resources is charged with implementing the MMPA and the ESA with respect to marine mammal species under the NOAA Fisheries jurisdiction which includes whales, dolphins, porpoises, seals, and sea lions. These efforts are relevant to this plan/EIS because ORVs are often used to respond to stranded marine mammals, and can be essential for quick and humane response. These actions are coordinated by NOAA and/or the Seashore with government vehicles, and are considered beneficial for the protection and management of marine mammals on the Seashore. ORVs also have the potential to impact resting or stranded marine mammals due to the fact that ORVs facilitate access to and increase visitor presence in relatively remote sections of the beach, which could bring people and vehicles into direct, short-term contact with resting or stranded marine mammals. This increases the potential for resting or stranded marine mammals to be disturbed or harassed. For example, harassment of resting seals has been documented numerous times on the Seashore, and ORVs will most likely continue to contribute to this as the area's winter seal population continues to increase.

### **Cape Lookout National Seashore Interim Protected Species Management Plan / Environmental Assessment and Off-Road Vehicle Management Plan / Environmental Impact Statement**

Located south of Ocracoke Inlet, Cape Lookout National Seashore also developed an interim protected species management plan / environmental assessment. The Cape Lookout National Seashore Interim Protected Species Management Plan / Environmental Assessment will guide management practices for the protection of special status species occurring at Cape Lookout National Seashore until a long-term ORV management plan/EIS and regulation is developed. Prior to the implementation of the interim protected species management plan in 2007, Cape Lookout conducted a range of species management activities that were less protective, but still provided a level of protection to the Seashore's federally listed species, state-listed species, and species of special concern through species monitoring and management and protective buffers. Cape Lookout National Seashore is developing a long-term ORV management plan/EIS. The Cape Lookout National Seashore ORV Management Plan/EIS is being developed during the same timeframe as the Cape Hatteras National Seashore ORV management plan/EIS, and will cover similar issues.

### **RELATIONSHIP TO OTHER STATE AND LOCAL PLANNING DOCUMENTS, POLICIES, ACTIONS, LAWS, AND REGULATIONS**

The following state and local documents, policies, actions, laws, and regulations are directly or indirectly related to ORV use, and were therefore considered during the development of this plan/EIS.

#### **North Carolina Division of Marine Fisheries Regulations**

Recreational fishing at the Seashore is guided by the North Carolina Division of Marine Fisheries regulations. The North Carolina Division of Marine Fisheries manages all marine and estuarine resources in the state. As part of this function, the division publishes an annual recreational fishing guide that sets minimum lengths and bag limits for various species. Beginning January 1, 2007, the State of North Carolina required recreational anglers to have a license for saltwater fishing.

#### **North Carolina Wildlife Resources Commission Nongame and Endangered Wildlife Program**

The Nongame and Endangered Wildlife Program, established in North Carolina in 1983, aims to prevent species from becoming endangered through maintaining viable, self-sustaining populations of all native wildlife, with an emphasis on species in decline. The NCWRC has a Comprehensive Wildlife Strategy to

protect state-listed species. This strategy includes securing funding for state fish and wildlife agencies to take preventative actions that help keep rare species from becoming endangered, and keep common species common (NCWRC 2005). Species listed through this program as state threatened, endangered, or of special concern were taken into consideration during the development of this plan/EIS. Endangered and threatened wildlife and wildlife species of special concern are protected under Article 25 of chapter 113 of the *North Carolina General Statutes*.

### **North Carolina Wildlife Resource Commission Handbook for Sea Turtle Volunteers in North Carolina**

The NCWRC published the Handbook for Sea Turtle Volunteers in North Carolina (NCWRC 2006). The handbook provides guidance to volunteers in conducting biologically sound management projects to benefit sea turtles and to help ensure compliance with laws pertaining to rare and endangered species at all levels of government. An annual permit is issued to the Seashore by the NCWRC under the authority of the USFWS. This handbook was considered in the development of this plan/EIS because turtle management is guided by this document.

### **North Carolina Natural Heritage Program**

Among other responsibilities, the North Carolina Natural Heritage Program (NCNHP) identifies the most important places for the conservation of rare species and high quality natural communities in the state. As of January 2008, the NCNHP had identified more than 2,400 of these places, officially referred to as Significant Natural Heritage Areas (SNHAs). If a natural area cannot be purchased by NCNHP, its ecological significance can be recognized through a registry agreement, which is a voluntary agreement with the landowner that provides limited protection but recognizes the owner's commitment to conservation of the area. There are 10 SNHAs located within the boundaries of the Seashore. The NPS signed two agreements with NCNHP for the formal protection of nine of these areas. The Buxton Woods SNHA was registered in 1979 and eight other SNHAs were registered in the 1987 agreement. The purpose of the agreements was to "express the sincere intentions of the National Park Service to refrain from making or permitting changes that negatively affect the natural values for which this area was registered within the boundaries outlined." It specifically stated, "Vehicular traffic on beach locations will be regulated to prevent damage to nesting colonies of water birds." The registered SNHAs potentially relevant to this plan/EIS are Turtle Pond and Cape Hatteras Lighthouse Pond, Cape Hatteras Point, Hatteras Sand Flats, Ocracoke Island - Eastern End, and Ocracoke Island - Western End Sand Flats. The unregistered Hatteras Island - Middle Section SNHAs is also in the Seashore. The significance of these SNHAs is primarily the habitat that they provide for shorebirds such as piping plover, American oystercatchers, and several species of colonial waterbirds, although several sensitive plant communities are also identified as part of these ecological communities. All of the action alternatives in this EIS provide increased levels of shorebird protection than what was occurring at the time the NPS and NCNHP signed the agreement to register and protect these natural areas. However, at this time, the exact on-the-ground location of any proposed improvements is not known, although general locations have been identified for each alternative in chapter 2 of this document. The NPS will consult with NCNHP when the Seashore begins the process to identify exact locations for constructing or relocating ramps, interdunal roads, or parking lots that are in an SNHA to ensure that the construction avoids impacts to any sensitive species.

### **North Carolina Department of Transportation**

The North Carolina Department of Transportation (NCDOT) has various projects related to NC-12 and other Outer Banks access issues. The NCDOT is considering some long-term projects in response to the changing physical landscape of the area such as a bridge from Avon to Buxton, which is a possible area

for a future inlet. The Outer Banks Task Force has developed a long-term management plan for NC-12 that was considered during the development of this plan/EIS. NC-12 connects the communities located within Cape Hatteras National Seashore to the mainland of North Carolina. Island residents depend on the roadway for off-island community services, such as hospitals, emergency response, and waste collection. NC-12 is also the primary evacuation route for all permanent and temporary residents on the island when severe weather is approaching. Storms frequently cause the ocean to overwash NC-12 and deposit large quantities of sand over portions of the roadway. The storms sometimes damage NC-12, which interrupts access and services to the island and causes hardships for island residents. NC-12 must be continually repaired and maintained to prevent permanent loss of access on Hatteras Island. To address these issues a task force was formed comprising the NCDOT, NPS, U.S. Army Corps of Engineers (Corps), USFWS, NMFS, Federal Highway Administration (FHWA), Dare and Hyde counties, and the NCDENR. The mission of this task force is to develop a long-range protection and maintenance plan for the transportation system on the Outer Banks. As part of this task force, hot spots for erosion have been identified and include Northern Pea Island, Sandbag area, Rodanthe “S” curves, Buxton / Canadian Hole, Hatteras Village, and Ocracoke (OBTF 2009).

The NCDOT is proposing to build a new bridge to replace the existing Herbert C. Bonner Bridge, originally built in the 1960s, over Oregon Inlet before the end of the bridge’s reasonable service life. The NCDOT and the FHWA released a supplemental draft EIS regarding this replacement, and a supplement to the EIS was released in 2007 (OBTF 2007; FHWA 2007). In September 2008, NCDOT announced its preferred alternative, known as the Parallel Bridge with Phased Approach / Rodanthe Bridge Alternative. This alternative includes constructing a new Oregon Inlet bridge (Phase I) west of the existing structure, and later elevating NC-12 onto a series of bridges during Phases II-IV. Replacement of the Oregon Inlet bridge is expected to be complete in 2014 (NCDOT 2008).

#### **North Carolina Coastal Area Management Act**

Details regarding the CAMA were presented earlier in this document under the CZMA description on page 40.

#### **Dare and Hyde County Planning Documents**

The development and implementation of this plan/EIS considered the planning efforts of Dare and Hyde counties, primarily with respect to the cumulative impacts analysis and consistency determination. Since 1974, when the North Carolina General Assembly ratified the CAMA, each of the local governments in the twenty-county coastal region have been developing and updating land use plans. These land use plans have directed development in these areas and are responsible for the pattern of development we see today in Dare and Hyde counties. Both of these plans recognize the development that has occurred and the corresponding need for an increase in services as a result. These past patterns of land use development have influenced the amount of land available for habitat throughout the county, including portions of the counties located within the Seashore.

In Dare County, the County Planning Board serves as an advisory board to the Dare County Board of Commissioners. In compliance with the CAMA, Dare County prepared guidance and policies for land use development, known as the Land Use Plan (Dare County 2003), which provides local elected officials with a set of guidelines for development patterns and other land use issues that are important to the community. The Land Use Plan includes policies on various topics and implementation activities such as policies on water quality, residential and commercial development patterns, beach access, oceanfront and estuarine development, stormwater management, wastewater, and transportation. The latest version of the Dare County Land Use Plan was certified by the North Carolina Coastal Resources Commission in July 2003, and must be updated every five years. The 2008 plan update was submitted to the state for review

in mid-January 2009 and as of February 1, 2010, was still under review (Owens pers. comm. 2010). The Land Use Plan applies to the unincorporated portions of Dare County, while each of the municipalities in Dare County adopts its own plans for its respective planning jurisdiction. The Dare County Land Use Plan works in conjunction with the zoning ordinance, as well as the CAMA. Except for the mainland villages and Wanchese, the remainder of unincorporated Dare County is zoned. Detailed zoning maps have been adopted for the villages of Duck, Collington, Roanoke Island, Avon, Buxton, and Hatteras. The villages of Rodanthe, Waves, Salvo, and Frisco are zoned S-1, which is a minimal zoning district that allows all uses but does establish some building setbacks and height limitations. In addition, the county adopted a Special Environmental District (SED-1) for the Buxton Woods maritime forest. This zoning district establishes special standards for land clearing and vegetation removal that are intended to protect the vegetative canopy of the Buxton Woods forest (Dare County 2003).

The Hyde County Land Use Plan, written in 1986, was updated in 1992, 1997, and 2006. Hyde County Land Use Plan, in compliance with the CAMA, analyzes land development in the area to plan for future uses. The plan sets forth the following vision for the Island of Ocracoke (Hyde County 2006).

The vision of Ocracoke Island in the 21st century is a community that ensures livability and economic viability by offering the discerning vacationer a preferable alternative to the over commercialized beach destinations while providing improved attention to Ocracoke residents. The mission of county government should be to facilitate and support:

- Efforts to maintain the historic village assets.
- Efforts to preserve traditional native occupations and crafts including hunting and commercial fishing.
- Efforts to enhance the Island shopping opportunities with small locally owned shops and businesses.
- Efforts to provide affordable housing.
- Cooperative efforts with the community, NPS, and DOT to maintain access to the Island and provide necessary amenities. Ocracoke and Mainland should emphasize access.
- Support village craftsmen.

### **Outer Banks Scenic Byway**

In the early 1990s, the NCDOT declared the Outer Banks corridor a state scenic byway. In September 2003, NCDOT completed an Outer Banks Scenic Byway Corridor Management Plan in preparation for seeking National Scenic Byway status. The Corridor Management Plan, updated in 2008, explored the “six intrinsic qualities” of the byway – scenic, natural, cultural, historic, archaeological, and recreational. The corridor management plan recognized the Seashore as one of the important natural components of the byway. The 2008 plan included recommendations for stewardship of the natural and cultural resources at the Seashore. Based on these planning efforts, the Outer Banks road corridor was officially designated as a National Scenic Byway on October 16, 2009.

### Off-Road Vehicle Regulations for Duck, Kill Devil Hills, Nags Head, Kitty Hawk, and Southern Shores

Each municipality on the Outer Banks has its own individual rules for ORV use. Generally all municipalities that allow beach driving share the following rules:

- ORV users are requested to observe a suggested speed limit of 15 miles per hour;
- ORVs users must enter and leave the beach only at designated ramps (never between ramps or on the dunes);
- ORVs should be driven only on the portion of beach that lies between the foot of the dunes and the ocean;
- ORV users are requested to proceed with caution and consideration of other beach visitors;
- ORVs must have a state road registration and valid license plate; and
- ORV operators must have a current driver's license.

In addition to these general guidelines, the surrounding municipalities have individual ORV regulations, as shown in table 6.

**TABLE 6. ORV REGULATIONS FOR OUTER BANKS MUNICIPALITIES**

Regulation/Guideline	Duck	Kill Devil Hills	Nags Head	Kitty Hawk and Southern Shores <sup>a</sup>
Observe 15 miles-per-hour (mph) speed limit	X	X	X	
Use designated ramps to enter/exit the beach	X	X	X	
Drive only between foot of dunes and ocean	X	X	X	
Be cautious/considerate of other visitors	X	X	X	
Vehicle must be registered with valid license plate	X	X	X	
Operator must have current license	X	X	X	
No permit is required between October 1 and April 30	X	X		
Vehicle must have 4-wheel drive		X		
Night driving is permitted		X		
Government, law enforcement, emergency, rescue services exempt	X	X	X	X
Commercial fishermen exempt				X
ORV must be permitted by regulations governing ORVs			X	

<sup>a</sup> No motorized vehicles are allowed on beaches at Kitty Hawk and Southern Shores except for commercial fishermen and government/emergency vehicles.

## CHAPTER 2: ALTERNATIVES

NEPA requires federal agencies to explore a range of reasonable alternatives that address the purpose of and need for the action. The alternatives under consideration must include the “no-action” alternative as prescribed by 40 CFR 1502.14. Two no-action alternatives are included for analysis in this plan/EIS, because management changed partway through the planning process in May 2008, after the consent decree was signed (see chapter 1 of this document for more information). Action alternatives may originate from the proponent agency, local government officials, or members of the public at public meetings or during the early stages of project development. Alternatives may also be developed in response to comments from coordinating or cooperating agencies.

The alternatives analyzed in this document, in accordance with NEPA, are the result of internal scoping, public scoping meetings, and information developed during the negotiated rulemaking process. Public and agency comments on the draft plan/EIS were analyzed and considered. As a response to these comments, NPS has made changes to the alternatives, where appropriate, which are reflected in this final plan/EIS. A copy of the original draft plan/EIS showing all additions, deletions, and other changes that have been made in the preparation of this final /EIS, including changes to the alternatives, is available electronically at <http://parkplanning.gov/caha>.

The action alternatives meet the management objectives of the Seashore, while also meeting the overall purpose of and need for proposed action. Alternative elements that were considered but were not technically or economically feasible, did not meet the purpose of and need for the project, created unnecessary or excessive adverse impacts to resources, and/or conflicted with the overall management of the Seashore or its resources were dismissed from further analysis.

The NPS explored and evaluated six alternatives in this plan/EIS, as follows:

- **Alternative A: No Action—Continuation of Management under the Interim Protected Species Management Strategy.** Under this no-action alternative, management of ORV use and access at the Seashore would be a continuation of management based on the 2007 Cape Hatteras National Seashore Interim Protected Species Management Strategy/EA and the Superintendent’s Compendium 2007, as well as elements from the 1978 draft interim ORV management plan that were incorporated in Superintendent’s Order 7.
- **Alternative B: No Action—Continuation of Terms of Consent Decree Signed April 30, 2008, and amended June 4, 2009.** Under alternative B, management of ORV use would follow the terms described under alternative A, except as modified by the provisions of the consent decree, as amended. Modifications in the consent decree include changes to resource protection buffers and closures for various species at the Seashore and added restrictions related to night driving.
- **Alternative C: Seasonal Management.** Alternative C would provide visitors to the Seashore with a degree of predictability regarding areas available for ORV use, as well as vehicle-free areas, based largely on the seasonal resource and visitor use characteristics of various areas in the Seashore.
- **Alternative D: Increased Predictability and Simplified Management.** Under alternative D, visitors to the Seashore would have the maximum amount of predictability regarding areas available for ORV use and vehicle-free areas for pedestrian use. Restrictions would be applied to larger areas over longer periods of time to minimize changes in designated ORV and vehicle-free areas over the course of the year.

- **Alternative E: Variable Access and Maximum Management.** Alternative E would provide use areas for all types of visitors to the Seashore with a wide variety of access for both ORV and pedestrian users, but often with controls or restrictions in place to limit impacts on sensitive resources. Interdunal road and ramp access would be improved, and more pedestrian access would be provided through substantial additions to parking capacity at various key locations that lend themselves to walking on the beach.
- **Alternative F: The NPS Preferred Alternative.** The NPS considered a variety of concepts and measures that either originated during the negotiated rulemaking process from members of the negotiated rulemaking advisory committee (Committee) or were discussed during Committee, subcommittee, or work group sessions. Although the Committee as a whole did not reach a consensus on a recommended alternative, in creating this action alternative the NPS made management judgments as to which combination of concepts and measures would make an effective overall ORV management strategy. This alternative is designed to provide visitors to the Seashore with a wide variety of access opportunities for both ORV and pedestrian users. Alternative F would provide a reasonably balanced approach to designating ORV routes and vehicle-free areas, while providing for the protection of park resources. To support access to both vehicle-free areas and designated ORV routes, alternative F would involve the construction of new parking areas, pedestrian access trails, ORV ramps, and improvements and additions to the interdunal road system. Based in part on public and agency comments on the draft plan/EIS, this alternative has been modified within the range of alternatives described in the draft plan/EIS.

## ELEMENTS COMMON TO ALL ALTERNATIVES

The following describes elements of the alternatives that are common to all alternatives, including the no-action alternatives.

### Vehicle/Operator Requirements

- **Vehicle Requirements.** All vehicles operating in any area of the Seashore must comply with the following:
  - Meet all requirements to operate legally on state highways where the vehicle is registered, including any required vehicle equipment.
  - Have a valid vehicle registration, insurance, and license plate.
- **Operator Requirements.** Any person operating a vehicle in any area of the Seashore must comply with the following:
  - Observe any law applicable to vehicle use on a paved road in the state of North Carolina.
  - Hold a current driver's license (Superintendent's Compendium, Section 4.2(a)).
  - Use a seatbelt.
- **Operator and Passenger Requirements.** Any vehicle operator and/or passenger in a vehicle operating in any area of the Seashore must comply with the following:
  - Open containers of any type of alcoholic beverage are prohibited in vehicles.
  - ORV drivers and/or passengers are prohibited from sitting on the tailgate or roof or hanging outside of moving vehicles. Those in truck beds must be seated on the floor with the tailgate closed; children in truck beds must be accompanied by an adult.

- **Right-of-Way Requirements.** Right-of-way between vehicles is not defined by the Seashore, and the standard driving rules must be followed.

### **Ramp Configuration**

- If Bonner Bridge construction closes ramp 4, a new ramp 3 would be constructed north of the Oregon Inlet campground and day-use parking would be provided.

### **Boat Access**

- Launch sites, as designated under 36 CFR 3.8(a)(2), are identified in the Superintendent's Compendium. Launching or recovery of vessels is prohibited within resource closures.

### **National Park Service Regulations**

Title 36: Parks, Forests, and Public Properties of the U.S. Code of Federal Regulations is applicable in all national parks, including Cape Hatteras National Seashore. These regulations include those in Title 36 applicable to the operation of ORVs in the Seashore and those applicable to individuals recreating at the Seashore. Of particular note are the provisions of 36 CFR 1.5 and 1.6, which state that the superintendent may impose public use limits, or close all or a portion of a park area to all public use or to a specific use or activity; designate areas for a specific use or activity; or impose conditions or restrictions on a use or activity, and may establish a permit, registration, or reservation system.

### **Enforcement**

Violations could result in fines or mandatory court appearances as defined in the Collateral Schedule, Eastern District of North Carolina, National Park Service.

### **Areas of Vehicle Operation**

During the shorebird and turtle breeding seasons, standard resource protection buffers would apply, which could restrict ORV access to certain areas of the Seashore. Refer to table 37-2 on page 295 of this document for a description of access closures that occurred during the 2007-2010 seasons.

Visitors accessing the Seashore by ORV must drive only on marked ORV routes, comply with posted restrictions, and adhere to the following:

- Driving or parking outside of marked and maintained ORV routes is prohibited.
- Operating a vehicle of any type within safety or resource closures is prohibited.
- Accessing the beach and designated ORV routes is allowed only via designated beach access ramps and soundside access roads.
- Reckless driving—for example, cutting circles or defacing the beach—is prohibited.
- Observing pedestrian right-of-way is required.

### **Commercial Fishing / Permitted Uses**

- Commercial fishing permit holders with ORVs would be allowed to enter administrative and safety closures, but not resource closures or lifeguarded beaches. Two designated commercial

fishing access points exist on the soundside of Ocracoke Island, where only vehicular access for commercial fishing is allowed.

- Kite flying, kiteboards, and ball and Frisbee tossing are prohibited within or above all bird closures.

### Protected Species Management

- In general, because of the dynamic nature of the Seashore beaches and inlets, protected species management could change by location and time; new sites (bars, islands) could require additional management, or management actions may become inapplicable for certain sites (e.g., habitat changes with vegetation growth, new overwash areas).
- Areas with symbolic fencing (string between posts) would be closed to recreational access.
- Data collection would continue to document breeding and nest locations.
- Essential vehicles could enter restricted areas subject to the guidelines in the Essential Vehicles section of the USFWS Piping Plover (*Charadrius melodus*), Atlantic Coast Population, Revised Recovery Plan (USFWS 1996a). Due to the soft sand conditions of the Seashore, essential vehicles would be allowed to travel up to 10 mph.

### Accessibility for Visitors with Disabilities

The Seashore would provide access to visitors with disabilities as follows:

- Beach access points and boardwalks would be provided at Coquina Beach, the Frisco Boathouse, the Ocracoke Pony Pen, and the Ocracoke day use area.
- Beach access would be provided through the issuance of special use permits for areas in front of the villages to allow ORVs to transport visitors with disabilities to the beach and then return the vehicle back to the street.
- Beach wheelchairs could be checked out at each District on a first-come, first-served basis.

### Infrastructure

- The Seashore has four campgrounds at Oregon Inlet, Frisco, Cape Point, and Ocracoke. The campgrounds would be open seasonally. Dates the campgrounds open or close would be subject to change.
- Fishing piers are located near Frisco and at Avon and Rodanthe on Cape Hatteras Island, and a marina is located at Oregon Inlet on Bodie Island. These would continue to be available to the public.<sup>4</sup>

---

<sup>4</sup> The Frisco pier was closed for public safety reasons due to deteriorating conditions, and then further damaged by Hurricane Earl in September 2010. The future of this pier is not known at this time.

## Education and Outreach

Under all alternatives, the Seashore would continue to

- Post signage in the Seashore so information on beach closures and Seashore resources is readily available and presented in a clear manner to the public.
- Post signs regarding applicable ORV regulations at ORV access ramps, beach routes, and soundside areas.
- Notify the public of species management closures and beach access status through weekly resource and beach access reports, press releases, email updates, and postings at the Seashore visitor centers and other NPS visitor facilities and on the Seashore website.
- Provide education and outreach materials regarding protected species (including seabeach amaranth) and measures taken by the Seashore to protect nesting birds and sea turtles at Seashore visitor centers and other NPS visitor facilities, on ORV access ramp bulletin boards, in the Seashore newspaper, and on the Seashore website. These materials include regulations regarding trash disposal, wildlife feeding, fireworks, and pets, and the impacts of such activities on sensitive Seashore species.
- Provide education and outreach materials regarding visitor safety at Seashore's visitor centers and other NPS visitor facilities, on ORV access ramp bulletin boards, in the Seashore newspaper, and on the Seashore website.
- Provide education and outreach materials regarding ORV-driving requirements at Seashore visitor centers and other NPS visitor facilities, on ORV access ramp bulletin boards, in the Seashore newspaper, and on the Seashore website.
- Solicit input from interested parties regarding how to convey information about the species management program.
- Conduct educational programs during the bird and sea turtle hatching season, such as having public school students participate in post-hatching sea turtle nest examinations in order to learn about sea turtles.
- Publish annual protected species reports on the Seashore website regarding the previous breeding season.

## NO-ACTION ALTERNATIVES

The no-action alternative is developed for two reasons. First, a no-action alternative may represent the agency's past and current actions or inaction on an issue continued into the future, which may represent a viable alternative for meeting the agency's purpose and need. Second, a no-action alternative may serve to set a baseline of existing impacts continued into the future against which to compare the impacts of action alternatives. For most agency decisions, one no-action alternative can serve both of these purposes. Here, however, the situation is more complex.

As stated in chapter 1, "in order to provide continued visitor access through the use of ORVs, NPS must promulgate a special regulation authorizing ORV use at the Seashore," and the purpose of this plan is to develop such a regulation. Without a special regulation, continued ORV use would conflict with NPS regulations (36 CFR 4.10). The consent decree recognizes this and sets a deadline of April 1, 2011, for the promulgation of a final special regulation. As the district court has recognized in another case, absent an ORV plan and regulation, as a legal matter ORV use is "prohibited." The NPS acknowledges that if it

does not promulgate a special regulation to authorize ORV use, then ORV use would, in fact, be prohibited at the Seashore.

“No ORV use” thus could represent a result of NPS past inaction continued into the future, and thus might satisfy the first purpose of a no-action alternative. It is not, however, a viable alternative for meeting the purpose and need for this action. It was considered but dismissed in the broader range of alternatives that were identified. See page 82 for a discussion of the reasons that, for this plan/EIS, “Prohibit the Use of Off-Road Vehicles” is not considered a reasonable alternative.

NPS also does not believe that a “no ORV use” alternative would fully serve the function of a no-action alternative, because it would not satisfy the second purpose. It would not serve as an environmental baseline of existing impacts continued into the future against which to compare the impacts of action alternatives. ORV use has occurred continuously before and since the Seashore was authorized and established. Given this history, a complete ORV prohibition cannot be considered as the “current management direction or level of management intensity” or as “continuing with the present course of action,” which is how CEQ describes this role of the “no-action” alternative under NEPA.

Because there is no history of prohibition at the Seashore, there is also no Seashore monitoring data for an analysis of its effects. Extrapolation from other sites that prohibit ORV use, and from experience with resource closures in limited locations and limited times at the Seashore, indicates that prohibition would likely benefit the Seashore’s wildlife more than the other alternatives, though benefits could be similar to those from alternative D. Prohibition would be easier for the Seashore to administer than the other alternatives, though it might increase the need for additional parking areas, with their attendant costs and effects. It would detract from the experience of those visitors who prefer ORVs for access, while enhancing the experience of other visitors who prefer beaches without the presence of vehicles. Prohibition would adversely affect the economies of the villages in the Seashore more than the other alternatives because ORV users would not have the opportunity to shift their visits to different areas of the Seashore or to different dates or times of day when driving would be allowed. These conclusions, however, are largely speculative and cannot substitute for a baseline of existing impacts.

Similarly, using the management measures enforced in 2004 (which were adopted from the 1978 draft plan) as a no-action alternative would fail to meet the agency’s purpose and need to regulate ORVs in a manner that is consistent with applicable law, and would not appropriately address resource protection (including protected, threatened, or endangered species), potential conflicts among the various Seashore users, and visitor safety. In addition, it would neither bring the Seashore into compliance with the criteria of Executive Orders 11644 and 11989 for designation of ORV routes nor meet the second purpose of a “no-action” alternative to serve as a baseline of existing impacts continued into the future against which to compare the impacts of action alternatives.

For this plan/EIS the range of alternatives includes two no-action alternatives. Alternative A represents continuing management as described in the Interim Strategy. This management strategy was challenged in court and subsequently modified by the consent decree that was signed on April 30, 2008. Alternative B represents continuing management as described in the consent decree. These two no-action alternatives are analyzed to capture the full range of management actions that occurred and are currently occurring during the planning process for this plan/EIS. Tables 7 and 8 at the end of this chapter compare the actions that would be taken under each alternative, and figure 2 includes the maps of all alternatives.

## **ALTERNATIVE A: NO ACTION—CONTINUATION OF MANAGEMENT UNDER THE INTERIM PROTECTED SPECIES MANAGEMENT STRATEGY**

Under this no-action alternative, management of ORV use and access at the Seashore would be a continuation of management based on the selected alternative identified in the July 2007 Finding of No Significant Impact (FONSI) for the 2006 Interim Strategy and the 2007 Superintendent's Compendium, as well as elements from the 1978 draft interim ORV management plan that were incorporated in Superintendent's Order 7, as amended in 2006. These actions would include providing ORV access throughout the Seashore, except in areas of temporary resource, safety, or administrative closures. Under alternative A, all the ocean and inlet shoreline and existing soundside routes would be designated as a route or area and would be open 24 hours a day year-round, but subject to temporary resource closures, seasonal ORV closures in front of the villages, and temporary ORV safety closures. As described in the FONSI, the Interim Strategy provides for the use, if feasible and if alternative routes are not available, of short-term bypasses when resource closures for shorebirds block the ORV corridor at Cape Point and the spits, and when a turtle nest hatching could lead to the blocking of access to the spits, Cape Point, or South Beach. The FONSI describes the following criteria for bypasses:

- a. The bypass area will be routed around dunes and vegetation if possible. If necessary, ground leveling, consistent with the state coastal management program, may be considered if dune fields do not exceed 36 inches in height. Leveling will be done by hand (no machinery will be used).
- b. The bypass will take advantage of natural terrain (e.g., blowouts) to minimize ground altering disturbance to the natural areas and avoid impacts to wetlands.
- c. The bypass will be at a minimum wide enough to allow one ORV to safely pass, and a maximum of two lanes if "line of sight" vision is compromised.
- d. Natural area disturbance to accommodate avoidance of turtle or bird nesting will not exceed 6,000 square feet.
- e. Minimal vegetation impact will be allowed.
  - Federal or state-listed plants or plants falling under the category of special concern (e.g., seabeach amaranth, dune blue curls) will not be compromised.
  - Vegetation in altered areas will be expected to recover within the following growing season. If vegetation does not recover within one growing season, or by other natural process (such as overwash creating habitat), the Seashore will initiate restoration of vegetation.
  - Any vegetation removal will be performed with hand tools (no machinery will be used).

Areas will be restored if predicted recovery period exceeds one season. Bypass routes will not infringe upon or fragment an adjacent resource/safety closure. Bypass routes will not disturb or impact any cultural resource (i.e., shipwrecks).

Vehicles would be allowed on the beach overnight only if someone associated with the vehicle is actively fishing. The ORV corridor would be marked by posts placed approximately 150 feet landward from the average, normal high tide line, or if less than 150 feet of space is available, at the vegetation or the toe of the remnant dune line, except during breeding season in protected species areas. Existing ORV safety closures would be maintained and new closures established as needed to address safety conditions such as debris on the beach or narrow beaches. Narrow beaches would be reopened as the beach widens. The beach in front of Cape Hatteras Lighthouse and Buxton Woods Road would remain closed to ORV access

for administrative purposes. Suitable interior habitats for piping plovers at spits and at Cape Point would be closed year-round to all recreational users to provide for resting and foraging for all species.

This no-action alternative would not require vehicles to have permits and would not involve any carrying-capacity restrictions. The speed limit would be 25 mph (unless otherwise posted) on Seashore beaches for public and private vehicles, although the speed limit in front of villages from September 16 to May 14 would be 10 mph. There would be no increase in parking facilities associated with this alternative. Under this no-action alternative, all the ocean and inlet shoreline and existing soundside routes would, for purposes of the rulemaking process, be a designated route or area, subject to temporary closures. Alternative A is analyzed as a baseline for comparison with the other alternatives in the plan/EIS following the requirements in 40 CFR 1502.14(d). Details of the management actions under this alternative are described in tables 8 and 9.

### **ALTERNATIVE B: NO ACTION—CONTINUATION OF TERMS OF THE CONSENT DECREE SIGNED APRIL 30, 2008, AND AMENDED JUNE 4, 2009**

A consent decree was signed on April 30, 2008, in U.S. District Court, whereby the parties involved in the lawsuit challenging NPS's management of beach driving under the Interim Strategy along Cape Hatteras National Seashore agreed to a settlement of the case. Terms of the consent decree required the NPS to complete an ORV Management Plan for the Seashore by December 31, 2010, complete and promulgate the final Special Regulation by April 11, 2011, and provide details of specific species-protection measures to take place until the plan was completed. Under alternative B, management of ORV use and access at the Seashore would be based on the management under alternative A, but modified by specific species-protection measures from the consent decree that are required until the ORV plan and final Special Regulation are completed. These management modifications included increasing the size of the buffers provided to various species at the Seashore, as well as adding restrictions related to night driving. On June 4, 2009, the following changes were made to the consent decree, as approved by the courts and agreed to by the parties involved in the lawsuit and settlement:

- Commercial fishermen would be granted access to beaches at 5:00 a.m. instead of 6:00 a.m., provided certain conditions from the modified consent decree are met.
- After September 15, all unhatched turtle nests would only require full beach closures from sunset until 6:00 a.m., instead of 24 hours a day.
- The NPS would not be required to expand a buffer for vandalism if the violator is apprehended. If the buffer has been expanded and then the violator is caught, the NPS can retract the expansion.

All other provisions in the consent decree remain the same. Under alternative B, beaches would be closed to all ORV use between the hours of 10:00 p.m. and 6:00 a.m. from May 1 to September 15, and open to ORV use from 10:00 p.m. to 6:00 a.m. with a permit from September 16 to November 15. This permit could be obtained online or at NPS offices or local tackle shops. From March 15 to November 30, an ORV-free zone at least 10 meters wide would be located in the ocean backshore wherever there is sufficient beach width to allow an ORV corridor at least 20 meters wide above the mean high tide line. Under alternative B, buffers for protected species would be larger than those identified in alternative A, and would include a required 1,000-meter buffer for unfledged piping plover chicks. In addition to ORV use, this 1,000-meter buffer would also apply to pets, as well as to kite flying, Frisbee throwing, and similar activities. Under this alternative, beach fires would be prohibited within 100 yards of turtle nest protection areas, as specified in the Superintendent's compendium. As in alternative A, suitable interior habitats for piping plovers at spits and at Cape Point would be closed year-round to all recreational users to provide for resting and foraging for all species. In case of a conflict between the Interim Strategy and

the measures described in the consent decree, the consent decree would prevail. Details of the management actions under this alternative are described in tables 8 and 9.

## **ACTION ALTERNATIVES**

The action alternatives would establish areas that allow ORV use and vehicle-free areas where ORV use is prohibited. Although ORV areas are specifically identified, these areas do not prohibit other uses, in effect making both ORV and vehicle-free areas multi-use recreation areas.

### **ELEMENTS COMMON TO ALL ACTION ALTERNATIVES**

The action alternatives, alternatives C, D, E, and F, provide a range of reasonable alternatives. The following describes elements of the management actions common to all the action alternatives.

#### **Ramp Configuration**

- A new ramp would be constructed at mile 32.5.
- Ramp 2 would be relocated approximately 0.5 mile south of Coquina Beach.

#### **Off Road Vehicle Access and Routes**

The following would apply:

- Visitors accessing the Seashore by ORV must use only designated beach access ramps and soundside access routes to enter designated ORV routes and areas.
- ORV operators must drive only on designated and marked ORV routes and must comply with posted restrictions.

#### **Seashore Management and Operations**

- Based on experience with implementing ORV management since 2007, staffing at the Seashore would need to increase under any action alternative to address basic functions of implementing an ORV management program. Staff would be hired to accomplish the following functions: coordination/management of the ORV program, coordination of science and adaptive management and resource education, and assistance with public information.

#### **Education and Outreach**

The Seashore would

- Improve signage related to beach closures and Seashore resources so that it is more readily available and presented in a clear manner to the public.
- Work with local organizations and businesses, including real estate rental agencies and hotels/motels, to ensure wider distribution of ORV and resource protection educational information. This would include encouraging these businesses to provide information about removal of beach equipment from the beaches at night.
- Provide information about and encourage the use of turtle friendly lighting.

- Encourage the Visitors Bureau and local tackle shops to link their websites to the Seashore's website to ensure that different segments of the visiting public have up-to-date information on beach closures and, if an ORV permitting system is developed, ORV permitting information.
- Develop a user-friendly ORV educational program (e.g., video or DVD) that could be administered as part of the ORV permitting process.
- Implement more educational programs in local schools and expand the Junior Ranger program to include more web-based options to interest youth in Seashore resources and stewardship.

### **Vehicle Requirements**

The following requirements would apply:

- Four-wheel drive would be recommended, although two-wheel-drive vehicles would be allowed.
- When driving on designated routes, operators would be required to lower tire pressure sufficiently to maintain adequate traction within the posted speed limit (20 pounds per square inch (psi) is recommended for most vehicles).
- Motorcycles would be prohibited on the ocean beachfront.
- There would be a limit on the number of axles allowed for vehicles and trailers.
- Only U.S. Department of Transportation listed and/or approved tires would be allowed.

### **Equipment Requirements**

- Vehicles would be equipped with a jack, jack support, shovel, and low-pressure tire gauge.

### **Speed Limits**

- The speed limit would be 15 mph, unless otherwise posted. Emergency vehicles would be exempt when responding to a call.

### **Parking Areas for Pedestrian Access**

- Any new parking areas would be located near vehicle-free areas and away from eroding areas or potential inlet areas.
- New parking areas would implement environmentally appropriate design standards to minimize stormwater runoff.
- New or expanded parking areas for ocean-side locations are identified in table 7 and table 7-1.

### **Beach Fires**

- Beach fires would be prohibited year-round during hours specified for each alternative in table 8. A permit would be required for all beach fires to ensure that users are informed of basic safety and resource protection measures. Where fires are permitted, they would be prohibited within 100 yards of turtle nest protection areas.

### **Nighttime Beach Use**

- Camping, as defined in 36 CFR 1.4, would be prohibited on Seashore beaches.
- Unattended beach equipment (chairs, canopies, volleyball nets, watersport gear, etc.) would be prohibited on the Seashore at night. Turtle patrol and law enforcement would tag equipment found at night. Owners would have 24 hours to remove equipment before it is removed by NPS staff.

### **Temporary Emergency Beach Closures**

- A temporary emergency beach closure may be implemented if any of the following conditions are observed:
  - ORV traffic backing up on the beach access ramps, either on- or off-beach bound, which threatens to impede traffic flow.
  - ORV traffic on the beach is parked in such a way that two-way traffic is impeded.
  - Multiple incidents of disorderly behavior are observed or reported.

### **Accessibility for Visitors with Disabilities**

- Some existing boardwalks would be retrofitted with accessible ramps to the extent that funding allows so visitors with disabilities can have more opportunities to access or view the beach. When new parking areas are developed, additional handicap parking spaces would be included, as appropriate.

### **Construction Measures**

- Prior to any construction under the action alternatives, wetland delineations would occur and wetland habitats would be avoided.

### **Species Management**

- Management of protected shorebirds would be accomplished through the implementation of the species management measures described in tables 10 and 10-1 at the end of this chapter.
- Management activities during the breeding season would focus on beach-nesting bird species such as the piping plover, Wilson's plover, American oystercatcher, least tern, common tern, gull-billed tern, and black skimmer; however, there would be ongoing evaluation of the breeding shorebird species addressed by this plan as part of the periodic review process.
- Prenesting areas for piping plover, American oystercatcher, Wilson's plover, and colonial waterbirds would be established in areas of suitable habitat that have had concentrated and recurring use by multiple individuals and/or multiple species of protected shorebirds during the breeding season in two or more of the past five years. Alternatives C, D, and E would not allow for ORV use in CWB prenesting areas, while alternative F would allow for ORV use on the lower beach until nesting activity occurs. These areas would be managed to reduce or minimize human disturbance. These areas would be re-evaluated as part of the periodic review process as described in tables 10 and 10-1.
- Areas of suitable nonbreeding habitat would be managed to reduce human disturbance during the nonbreeding season. This may include portions of prenesting areas that provide suitable

nonbreeding habitat during periods of overlap between the breeding and migrating season; designated vehicle-free areas that are set aside to provide pedestrians with the opportunity for a natural beach experience; and resource closures at some points and spits, based on an annual nonbreeding habitat assessment conducted after the breeding season.

- Management and monitoring protocols are provided for turtles and seabeach amaranth. Details of all species management strategies can be found in tables 10 and 10-1 at the end of this chapter.
- Incorporation of the Piping Plover Recovery Plan, Appendix G: Guidelines for Managing Recreational Activities in Piping Plover Breeding Habitat on the U.S. Atlantic Coast to Avoid Take Under Section 9 of the ESA. Appendix G of the Piping Plover Recovery Plan was used as a basis for determining appropriate management measures under all of the action alternatives. This document provides guidance to beach managers and property owners seeking to avoid potential violations of Section 9 of the ESA (16 USC 1538) and its implementing regulations (50 CFR 17) that could occur as the result of recreational activities on beaches used by breeding piping plovers along the Atlantic Coast. These guidelines were developed by the Northeast Region, USFWS (or Service), with assistance from the U.S. Atlantic Coast Piping Plover Recovery Team. The guidelines are advisory, and failure to implement them does not, of itself, constitute a violation of the law. Rather, they represent the USFWS best professional advice to beach managers and landowners regarding the management options that will prevent direct mortality, harm, or harassment of piping plovers and their eggs due to recreational activities. Appendix G makes the following recommendations:

*Management of Nonmotorized Recreational Use* – On beaches where pedestrians, joggers, sunbathers, picnickers, fishermen, boaters, horseback riders, or other recreational users are present in numbers that could harm or disturb incubating plovers, their eggs, or chicks, areas of at least 50 meter-radius around nests above the high tide line should be delineated with warning signs and symbolic fencing. Only persons engaged in rare species monitoring, management, or research activities should enter posted areas. These areas should remain fenced as long as viable eggs or unfledged chicks are present. Fencing is intended to prevent accidental crushing of nests and repeated flushing of incubating adults, and to provide an area where chicks can rest and seek shelter when large numbers of people are on the beach.

Available data indicate that a 50 meter buffer distance around nests will be adequate to prevent harassment of the majority of incubating piping plovers. However, fencing around nests should be expanded in cases where the standard 50 meter-radius is inadequate to protect incubating adults or unfledged chicks from harm or disturbance. Data from various sites distributed across the plover's Atlantic Coast range indicates that larger buffers may be needed in some locations. This may include situations where plovers are especially intolerant of human presence, or where a 50 meter-radius area provides insufficient escape cover or alternative foraging opportunities for plover chicks. In cases where the nest is located less than 50 meters above the high tide line, fencing should be situated at the high tide line, and a qualified biologist should monitor responses of the birds to passersby, documenting his/her observations in clearly recorded field notes. Providing that birds are not exhibiting signs of disturbance, this smaller buffer may be maintained in such cases. On portions of beaches that receive heavy human use, areas where territorial plovers are observed should be symbolically fenced to prevent disruption of territorial displays and courtship. Since nests can be difficult to locate, especially during egg-laying, this will also prevent accidental crushing of undetected nests. If nests are discovered outside fenced areas, fencing should be extended to create a sufficient buffer to prevent disturbance to incubating adults, eggs, or unfledged chicks. Pets should be leashed and under control of their owners at all times from April 1 to August 31 on beaches where piping plovers are present or have traditionally nested. Pets should be prohibited on these beaches from April 1 through August 31 if, based on observations and experience, pet owners fail to keep pets leashed and under control. Kite flying should be prohibited within 200 meters of nesting or territorial adult or unfledged juvenile piping plovers

between April 1 and August 31. Fireworks should be prohibited on beaches where plovers nest from April 1 until all chicks are fledged.

*Motor Vehicle Management* – The Fish and Wildlife Service recommends the following minimum protection measures to prevent direct mortality or harassment of piping plovers, their eggs, and chicks on beaches where vehicles are permitted. Since restrictions to protect unfledged chicks often impede vehicle access along a barrier spit, a number of management options affecting the timing and size of vehicle closures are presented here. Some of these options are contingent on implementation of intensive plover monitoring and management plans by qualified biologists. It is recommended that landowners seek concurrence with such monitoring plans from either the Service or the State wildlife agency.

*Protection of Nests* – All suitable piping plover nesting habitat should be identified by a qualified biologist and delineated with posts and warning signs or symbolic fencing on or before April 1 each year. All vehicular access into or through posted nesting habitat should be prohibited. However, prior to hatching, vehicles may pass by such areas along designated vehicle corridors established along the outside edge of plover nesting habitat. Vehicles may also park outside delineated nesting habitat, if beach width and configuration and tidal conditions allow. Vehicle corridors or parking areas should be moved, constricted, or temporarily closed if territorial, courting, or nesting plovers are disturbed by passing or parked vehicles, or if disturbance is anticipated because of unusual tides or expected increases in vehicle use during weekends, holidays, or special events.

If data from several years of plover monitoring suggests that significantly more habitat is available than the local plover population can occupy, some suitable habitat may be left unposted if the following conditions are met:

1. The Service OR a State wildlife agency that is party to an agreement under Section 6 of the ESA provides written concurrence with a plan that:
  - A. Estimates the number of pairs likely to nest on the site based on the past monitoring and regional population trends.

AND

  - B. Delineates the habitat that will be posted or fenced prior to April 1 to assure a high probability that territorial plovers will select protected areas in which to court and nest. Sites where nesting or courting plovers were observed during the last three seasons as well as other habitat deemed most likely to be pioneered by plovers should be included in the posted and/or fenced area.

AND

  - C. Provides for monitoring of piping plovers on the beach by a qualified biologist(s). Generally, the frequency of monitoring should be not less than twice per week prior to May 1 and not less than three times per week thereafter. Monitoring should occur daily whenever moderate to large numbers of vehicles are on the beach. Monitors should document locations of territorial or courting plovers, nest locations, and observations of any reactions of incubating birds to pedestrian or vehicular disturbance.

AND

  2. All unposted sites are posted immediately upon detection of territorial plovers.

*Protection of Chicks* – Sections of beaches where unfledged piping plover chicks are present should be temporarily closed to all vehicles not deemed essential. (See the provisions for essential vehicles below.) Areas where vehicles are prohibited should include all dune, beach, and intertidal habitat within the chicks' foraging range, to be determined by either of the following methods:

1. The vehicle-free area should extend 1,000 meters on each side of a line drawn through the nest site and perpendicular to the long axis of the beach. The resulting 2000 meter-wide

area of protected habitat for plover chicks should extend from the ocean-side low water line to the bay-side low water line or to the farthest extent of dune habitat if no bay-side intertidal habitat exists. However, vehicles may be allowed to pass through portions of the protected area that are considered inaccessible to plover chicks because of steep topography, dense vegetation, or other naturally-occurring obstacles.

OR

2. The Service OR a State wildlife agency that is party to an agreement under Section 6 of the ESA provides written concurrence with a plan that:
  - A. Provides for monitoring of all broods during the chick-rearing phase of the breeding season and specifies the frequency of monitoring.

AND

- B. Specifies the minimum size of vehicle-free areas to be established in the vicinity of unfledged broods based on the mobility of broods observed on the site in past years and on the frequency of monitoring. Unless substantial data from past years show that broods on a site stay very close to their nest locations, vehicle-free areas should extend at least 200 meters on each side of the nest site during the first week following hatching. The size and location of the protected area should be adjusted in response to the observed mobility of the brood, but in no case should it be reduced to less than 100 meters on each side of the brood. In some cases, highly mobile broods may require protected areas up to 1000 meters, even where they are intensively monitored. Protected areas should extend from the ocean-side low water line to the bay-side low water line or to the farthest extent of dune habitat if no bay-side intertidal habitat exists. However, vehicles may be allowed to pass through portions of the protected area that are considered inaccessible to plover chicks because of steep topography, dense vegetation, or other naturally-occurring obstacles. In a few cases, where several years of data documents that piping plovers on a particular site feed in only certain habitat types, the Service or the State wildlife management agency may provide written concurrence that vehicles pose no danger to plovers in other specified habitats on that site.

*Timing of Vehicle Restrictions in Chick Habitat* – Restrictions on use of vehicles in areas where unfledged plover chicks are present should begin on or before the date that hatching begins and continue until chicks have fledged. For purposes of vehicle management, plover chicks are considered fledged at 35 days of age or when observed in sustained flight for at least 15 meters, whichever occurs first. When piping plover nests are found before the last egg is laid, restrictions on vehicles should begin on the 26th day after the last egg is laid. This assumes an average incubation period of 27 days, and provides a 1 day margin of error. When plover nests are found after the last egg has been laid, making it impossible to predict hatch date, restrictions on vehicles should begin on a date determined by one of the following scenarios:

1. With intensive monitoring: If the nest is monitored at least twice per day, at dawn and dusk (before 0600 hrs and after 1900 hrs) by a qualified biologist, vehicle use may continue until hatching begins. Nests should be monitored at dawn and dusk to minimize the time that hatching may go undetected if it occurs after dark. Whenever possible, nests should be monitored from a distance with spotting scope or binoculars to minimize disturbance to incubating plovers.

OR

2. Without intensive monitoring: Restrictions should begin on May 15 (the earliest probable hatch date). If the nest is discovered after May 15, then restrictions should start immediately.

If hatching occurs earlier than expected, or chicks are discovered from an unreported nest, restrictions on vehicles should begin immediately. If ruts are present that are deep enough to restrict movements of plover chicks, then restrictions on vehicles should begin at least 5 days prior

to the anticipated hatching date of plover nests. If a plover nest is found with a complete clutch, precluding estimation of hatching date, and deep ruts have been created that could reasonably be expected to impede chick movements, then restrictions on vehicles should begin immediately.

*Essential Vehicles* – Because it is impossible to completely eliminate the possibility that a vehicle will accidentally crush unfledged plover chicks, use of vehicles in the vicinity of broods should be avoided whenever possible. However, the Service recognizes that life-threatening situations on the beach may require emergency vehicle response. Furthermore, some “essential vehicles” may be required to provide for safety of pedestrian recreationists, law enforcement, maintenance of public property, or access to private dwellings not otherwise accessible. On large beaches, maintaining the frequency of plover monitoring required to minimize the size and duration of vehicle closures may necessitate the use of vehicles by plover monitors. Essential vehicles should only travel on sections of beaches where unfledged plover chicks are present if such travel is absolutely necessary and no other reasonable travel routes are available. All steps should be taken to minimize number of trips by essential vehicles through chick habitat areas. Homeowners should consider other means of access, e.g., by foot, water, or shuttle services, during periods when chicks are present. The following procedures should be followed to minimize the probability that chicks will be crushed by essential (non-emergency) vehicles:

1. Essential vehicles should travel through chick habitat areas only during daylight hours, and should be guided by a qualified monitor who has first determined the location of all unfledged plover chicks.
2. Speed of vehicles should not exceed five miles per hour.
3. Use of open 4-wheel motorized ATVs or nonmotorized all-terrain bicycles is recommended whenever possible for monitoring and law enforcement because of the improved visibility afforded operators.
4. A log should be maintained by the beach manager of the date, time, vehicle number and operator, and purpose of each trip through areas where unfledged chicks are present. Personnel monitoring plovers should maintain and regularly update a log of the numbers and locations of unfledged plover chicks on each beach. Drivers of essential vehicles should review the log each day to determine the most recent number and location of unfledged chicks.

Essential vehicles should avoid driving on the wrack line, and travel should be infrequent enough to avoid creating deep ruts that could impede chick movements. If essential vehicles are creating ruts that could impede chick movements, use of essential vehicles should be further reduced and, if necessary, restricted to emergency vehicles only.

- **Incorporation of the 2008 Loggerhead Sea Turtle Recovery Plan.** The following elements from the Loggerhead Sea Turtle Recovery Plan were considered in development of the action alternatives:

2225. Prohibit recreational equipment on nesting beaches at night. Sea turtles prefer to nest on the mid to upper beach, protecting their nests from repeated and prolonged high tides. Recreational equipment (e.g., beach furniture, umbrellas, marine craft, tents) that are left on the beach at night can prevent nesting turtles from reaching the mid to upper beach. Therefore, at night, all recreational equipment should be completely removed from the beach by hand and stored behind the primary dune. Regulations should be developed and enforced to ensure these types of impediments to nesting are managed or eliminated.

Maintain at least the current length and quality of protected nesting beach. As of 2007, 1,581 km of nesting beach in the U.S. were identified as being within conservation lands in public (Federal, state, or local government) ownership and privately owned conservation lands (e.g., non-profit conservation foundations). Most of these lands are generally managed in a way that benefits sea turtle conservation. Public lands that have lighted development, armoring, or other profound threats to sea turtle nesting have not been included. In compiling the list of conservation lands, human visitation was not considered a profound threat to sea turtle nesting.

Therefore, public lands designated for human recreation have been included. At a minimum, the amount of nesting beach in such protected status should be maintained.

251. Develop, fully implement, and effectively enforce light management plans to address direct and indirect (e.g., sky glow, uplighting) artificial lighting on nesting beaches.

2511. Implement and enforce lighting ordinances on lands under local government jurisdiction. Where lighting ordinances have been adopted and adequately enforced, hatchling disorientation has been managed at acceptable levels. All coastal counties and communities with nesting beaches should adopt and fully enforce ordinances from March through October in Brevard through Broward counties, Florida, and from May through October elsewhere. The State of Florida's Model Lighting Ordinance [<http://myfwc.com/seaturtle>] should be used as a template for developing new or revising existing lighting ordinances. In addition, Port Authorities should develop and enforce lighting management plans to ensure their direct and indirect lighting does not impact nesting and hatchling turtles on nearby beaches.

61. Minimize impacts to sea turtles on nesting beaches.

6113. Use the least manipulative method to protect nests. Until such time as a management plan for protecting nests is developed, the least manipulative method should be employed to protect nests. Because the incubation environment greatly influences the developing embryo, nest relocation can involve the transfer of eggs from an appropriate environment to an inappropriate one. As a general rule, nests should only be relocated if they are low enough on the beach to be washed daily by tides or if they are situated in well documented highrisk areas that routinely experience serious erosion and egg loss (e.g., nests laid near river mouths or beneath eroding sea walls).

Natural events, like storms, that accelerate beach erosion and accretion can sometimes reduce hatching success in existing nests. While damage from storm events can be severe, it is difficult to predict the precise areas where the storm is most likely to inflict damage. Because of the negative effects of relocating eggs and the unpredictability of storm events, nests should not be moved out of areas threatened by storms. Nests should not be relocated in areas where heavy foot traffic, lighting problems, or beach cleaning are a concern. Foot traffic generally is not a problem for nests, but depending on the nesting substrate, pedestrian traffic over nests near the time of emergence can cause the nests to collapse and result in hatchling mortality. Therefore, in areas where foot traffic is heavy, nests can be marked so pedestrians can avoid them. If a nest is made near a light that may misorient the hatchlings, efforts should focus on getting the light turned off or shielded (if protection is necessary, the nest should be caged). If nests are deposited on beaches that are periodically raked with mechanical equipment, beach raking should be discontinued or the nests should be marked clearly so they can be avoided by the beach cleaners.

6114. Discontinue the use of hatcheries as a nest management technique. Relocation of sea turtle nests to hatcheries located higher on the beach was once a common practice throughout the southeast U.S. to mitigate the effects of naturally occurring events, such as erosion and vegetation encroachment, predation, and a variety of human-induced factors. In some areas, the extent and type of coastal development have resulted in significant light pollution problems. As a result, a few hatcheries are still used to protect hatchlings from disorientation. However, relocating nests into hatcheries concentrates eggs in an area and makes them more susceptible to catastrophic events and predation from both land and marine predators. Therefore, in areas where hatcheries are still being used to protect nests and hatchlings from light pollution, management efforts should be shifted to eliminate the lighting problems and phase out the use of hatcheries. At Cape Romain [National Wildlife Refuge (NWR)] in South Carolina, hatcheries are being used as a last resort in response to severe erosion. In this case, the conservation benefits (i.e., embryo survivorship) are believed to outweigh the potential conservation risks (e.g., hatchling predation). Given these circumstances, the use of hatcheries at Cape Romain

NWR is currently considered appropriate until sufficient habitat for successful incubation is available. Continued use of hatcheries on the refuge should be based on periodic quantitative assessments of their effectiveness as a management tool.

6121. Prohibit nighttime driving on beaches during the loggerhead nesting season. Vehicles on the beach have the greatest potential to come into contact with nesting females and emerging hatchlings at night. In areas where beach driving is still allowed, nighttime vehicle use should be limited to essential vehicles (e.g., emergency or permitted research vehicles) only. When essential vehicles are allowed on the beach at night during the sea turtle nesting season, their potential for harming turtles should be minimized by driving at speeds of 5 miles per hour or less (except when higher speeds are necessary for law enforcement, human safety, or medical emergencies), and by driving seaward of the wrack or debris line or just above it during high tide conditions. In addition, regardless of the time of year, vehicles or equipment driven or used on the beach should be equal to or less than 10 pounds per square inch (psi) based on ground loading characteristics (e.g., all terrain vehicles) to minimize the potential for sand compaction.

6123. Manage daytime driving to minimize impacts to loggerheads. In addition to prohibiting nighttime driving of non-essential vehicles on the beach, other measures should be implemented to minimize the potential for impacts to sea turtles. Examples of minimization measures include the designation and enforcement of no-driving zones in areas where the greatest concentration of nests are typically located (e.g., conservation zones near the dunes), monitoring and marking of all sea turtle nests for avoidance, and developing and implementing a vehicle rut removal program seaward of nests during periods when hatchlings are expected to emerge.

614. Minimize harassment of nesting females and hatchlings. Resident and visitor use of nesting beaches can adversely affect nesting sea turtles, incubating egg clutches, and hatchlings. Intentional and unintentional disturbance and harassment of nesting females and hatchlings is an increasing problem on many beaches. Problem areas where repeated incidents of turtle harassment have been reported should be identified, and law enforcement efforts should be focused there.

6142. Conduct public education campaigns to minimize harassment of nesting females and hatchlings. Resident and visitor use of nesting beaches can adversely affect nesting sea turtles and hatchlings. The most serious threat caused by human presence on the beach is the disturbance of nesting females. Disturbance of nesting females can cause them to leave the beach without finishing nesting and thus delay egg laying, shift their nesting beaches, and select poor nesting sites. Hatchlings rely on a store of energy and nutrients within their retained yolk sac to make their way from the nest to their offshore developmental habitat. Any delays they encounter on the beach by pedestrians may impair their ability to migrate offshore. Beachgoers should be informed through presentations and educational materials about the potential impacts to sea turtles from pedestrians on the beach and how to avoid frightening or disorientating any nesting and hatchling turtles encountered. In addition, signage at access points to the beach is recommended to further inform residents and visitors about proper nesting beach etiquette.

6143. Increase the number of interpretive turtle walks to meet demand and minimize overall disturbance to nesting females and hatchlings. In the U.S., numerous state-permitted organizations conduct organized turtle walks to allow the public to view the nesting process. Thousands of coastal visitors and local residents attend these organized turtle watches each year; however, thousands more are turned away due to the limited number of walks available. As a result, numerous unsupervised individuals who were unable to get into a turtle walk often try to find turtles by themselves and inadvertently end up harassing them. Interpretive turtle walks also are a mechanism for garnering

support for sea turtle conservation through education and should be expanded to accommodate the high public demand for participation.

6144. Enforce laws to minimize harassment of nesting females and hatchlings. Intentional and unintentional disturbance and harassment of nesting turtles and hatchlings is an increasing problem on many beaches. Problem areas should be identified and law enforcement efforts should be focused in these areas to deter harassment of nesting turtles and hatchlings.

615. Develop and enforce guidelines for special events on the beach to minimize impacts on nesting females, nests, and hatchlings. A wide variety of special events (e.g., volleyball tournaments, concerts) take place on the beach. Some of these events considerably increase the number of people and equipment in a given area. Many events are scheduled outside of the sea turtle nesting period, but some do occur during the nesting season. State resource agencies and local governments should develop and enforce guidelines for special events that will occur during the nesting season to ensure there will be no direct or indirect impacts on nesting turtles, nests, and emerging hatchlings.

- Establishment of Buffer Distances.** The potential impacts of human disturbance on beach-nesting birds and their chicks are well documented and described in chapter 3 of this document. A buffer is an area surrounding a sensitive resource, such as bird nests or chicks, which is restricted (or closed) to visitor access during critical life cycle stages in order to reduce human disturbance and the risk of mortality due to pedestrians and ORVs. The sensitivity of beach-nesting birds to human disturbance varies by species and can vary among individual birds of the same species depending upon the circumstances. Buffer distances for managed species are detailed in table 11. The buffer distances identified in the action alternatives were developed after consideration of the best available science, which includes existing guidelines and recommendations, such as the Piping Plover Recovery Plan (USFWS 1996a) and the USGS Open-File Report 2009-1262 (2010) on the management of species of special concern at the Seashore, as well as relevant scientific literature (research, studies, reports, etc.) for the respective species. In addition, buffer distances were developed using the practical knowledge gained by NPS resources management staff during two years of implementing the Interim Strategy (2006–2007) and three years implementing the consent decree (2008–2010). In 2007 under the Interim Strategy, which identified the buffer distances that would be used under alternative A, NPS staff implemented a total of 126 shorebird management actions that involved establishing, modifying, or removing fencing around resource closures. In 2009 and 2010 under the consent decree, which identified the buffer distances that would be used under alternative B, NPS staff implemented a total of 202 and 164 shorebird management actions, respectively.

The buffer distances are intended to provide adequate protection to minimize the impacts of human disturbance on nesting birds and chicks in the majority of situations, given the level of visitation and recreational use in areas of sensitive wildlife habitat at the Seashore and issues related to non-compliance with posted resource protection areas. For example, under the action alternatives the buffer distance for nesting piping plovers is set at 75 meters, and would be expanded upon disturbance or when chicks are present. A 1992 study at Assateague Island National Seashore (Loegering 1992), a national seashore with a similar type of barrier island habitat and recreational use as Cape Hatteras, found that on average, incubating plovers flushed from their nests at a distance of 78 meters (256 feet), although some birds flushed when researchers were as far as 174 meters (571 feet) away. Researchers reported that the minimum agitation distance to nesting piping plover was 50 meters, and suggested a buffer radius of 225 meters. The recommended buffers for piping plover under this plan/EIS not only took into consideration the Piping Plover Recovery Plan, but also studies in similar environments such as Assateague Island. Buffers for the other bird species were developed in a similar manner, taking

into consideration the best available studies, combined with Seashore staff observations of how the species react in the specific environment of the Seashore. The action alternatives' buffers, when combined with the Species Management Areas (SMAs) under alternatives C, D, and E and the prenesting areas and vehicle-free areas for all action alternatives, are designed to be effective for species protection and operationally feasible to implement and sustain.

### **ORV Permits**

- Permits would be required for vehicular use on designated ORV routes.
- There would be no limit on the number of permits issued.
- Permits would be available at designated permit issuing stations.
- Permit stickers would be affixed to vehicles in a manner approved by the NPS.
- Permits could be revoked for violation of applicable Seashore regulations or terms and conditions of the permit.

## **ADAPTIVE MANAGEMENT APPROACHES INCLUDED IN THE ACTION ALTERNATIVES**

The Department of the Interior requires that its agencies “use adaptive management to fully comply” with CEQ guidance that requires “a monitoring and enforcement program to be adopted ... where applicable, for any mitigation” (516 DM 1.3 D (7); 40 CFR 1505.2). Adaptive management is based on the assumption that current resources and scientific knowledge are limited. Nevertheless, adaptive management attempts to apply available resources and knowledge and adjusts management techniques as new information becomes available.

Adaptive management incorporates scientific experimental methods into the management process while providing flexibility to adjust to changes in the natural environment. It is based on a continuing, iterative process of

- Applying management actions.
- Monitoring consequences.
- Evaluating monitoring results against plan objectives.
- Adjusting management.
- Using feedback to make future management decisions.

All action alternatives incorporate adaptive management initiatives (outlined in table 10 and table 10-1) that are designed to assist the Seashore in meeting the objectives of this plan/EIS and desired future conditions as outlined in chapter 1 of this document. These species-specific initiatives include implementing additional research and monitoring for piping plover, sea turtles, and seabeach amaranth, based on available funding. Information obtained from the implementation of adaptive management initiatives would be integrated into future decision making.

## **PERIODIC REVIEW UNDER THE ACTION ALTERNATIVES**

A systematic review of data, annual reports, and other information would be conducted by NPS every five years, after storms or events that Seashore management determines to be a major modification of habitat

quantity or quality, or if necessitated by a significant change in protected species status (e.g., listing or de-listing), in order to evaluate the effectiveness of management actions in making progress toward the accomplishment of stated objectives and desired future conditions (see chapter 1 of this document). Periodic review could result in changes to the management actions in order to improve effectiveness. When desired future conditions for resources are met or exceeded, periodic review and adaptive management may allow for more flexible management of recreational use, provided adverse impacts of such use are effectively managed and wildlife populations remain stable. Where progress is not being made toward goals, periodic review and adaptive management may result in increased restrictions on recreational use. Components subject to periodic review vary among the action alternatives.

## **DISCUSSION OF ACTION ALTERNATIVES**

### **ALTERNATIVE C: SEASONAL MANAGEMENT**

This alternative is designed to provide visitors to the Seashore with a degree of predictability regarding areas available for ORV use, as well as vehicle-free areas, based largely on the seasonal resource- and visitor-use characteristics of various areas in the Seashore. This alternative would manage ORV use by identifying areas that historically do not support sensitive resources or that historically have lower visitor use. Many of these areas would generally be designated as ORV routes year-round. Areas of high resource sensitivity and high visitor use would generally be designated as seasonal ORV routes, with restrictions based on seasonal resource and visitor use or as year-round vehicle-free areas. Some areas would be designated as vehicle free year-round to provide opportunities for non-ORV users to experience the Seashore without the presence of vehicles. The establishment of ORV routes and vehicle-free areas would be based largely on seasonal resource requirements and year-round visitation patterns and would provide the public and the Seashore with a structured management approach that clearly states what areas are available for ORV use and when they are open. The public would have clear direction as to what would be open seasonally or year-round; however, it would require some effort on the public's part to be informed and to understand what areas are open and when use is permitted. Implementation would require an increase in Seashore staff and resources for public education and enforcement, but would provide for efficient Seashore operations with the identification of defined use areas.

Generally, most areas where there is a seasonally designated ORV route would be open to ORVs from October 15 to March 14, primarily due to concerns about resource protection for birds and turtles during breeding and hatching/fledging periods and to minimize conflicts with high visitor use periods. Areas that would be seasonally designated vehicle free would include SMAs and some village beaches. These seasonal vehicle-free areas would primarily occur during periods of high visitation and high resource sensitivity—the summer and shoulder season months. The spits and points would be closed to ORVs from March 15 to October 14 to provide resource protection. A pedestrian access corridor would be provided at Bodie Island Spit, Cape Point, and South Point although the corridor could close during the breeding season as resource protection buffers and closures are established. Existing soundside ORV access areas would be retained and designated as ORV routes, including existing primitive parking and designated boat launch areas. The Seashore would maintain posts and signage defining the location of the parking areas and ORV access routes on the soundside.

ORV routes under this alternative would still be subject to temporary resource closures established when protected species breeding behavior warrants and/or if new habitat is created. In addition to the breeding season measures, resource closures and/or vehicle-free areas would be established, based on an annual nonbreeding habitat assessment conducted after the breeding season, to provide areas of nonbreeding shorebird habitat with reduced human disturbance while still allowing a pedestrian or pedestrian/ORV access corridor in areas designated by the NPS (common to all alternatives).

Designated ORV routes would be established seasonally in areas with high visitation and/or sensitive resources and year-round in some areas that historically do not support sensitive resources or that have lower visitor use. To facilitate ORV access to the designated routes, existing ramps would be improved, reconfigured, and/or supplemented by new ramps, including the construction of ramps 47, 48, 62, and 64. (Note: All action alternatives involve relocating ramp 2 and building a new ramp at 32.5.) In addition, the interdunal road network would be maintained at its current level of access in most places, although an extension from ramp 45 west to ramp 49 would be provided. Pullouts or road widening would be provided where appropriate to provide safe ORV passage on the interdunal roads. Designated ORV routes would be open to ORV use 24 hours a day from November 16 through April 30, although SMAs would be closed to ORV use beginning on March 15. From May 1 through November 15, all potential sea turtle nesting habitat (ocean intertidal zone, ocean backshore, and dunes) would be closed to non-essential ORV use from 7:00 p.m. to 7:00 a.m. This alternative also involves the addition or expansion of parking areas at several locations.

ORV safety closures would be designated as conditions warrant and would be evaluated for reopening by NPS law enforcement staff on a weekly basis. ORV safety closures would be applicable only to ORV access; pedestrian and commercial fishing access would generally be maintained through ORV safety closures.

Alternative C would include a Seashore-wide carrying-capacity element (“peak use limit”), which would be based on a physical space requirement of an average of one vehicle per 20 linear feet for Bodie and Hatteras Island Districts and one vehicle per 30 linear feet for the Ocracoke Island District. The provision of a lower carrying-capacity on Ocracoke Island would provide for a less crowded visitor experience in this area, enhancing the types of experiences available throughout the Seashore. The carrying capacity could be implemented whenever overcrowding could cause safety concerns, such as peak use periods during major summer holidays and weekends. The allowable number of vehicles in each area subject to the carrying capacity would be determined by the space requirements and the beachfront length of the area.

Alternative C would include an ORV permit system, with no limit on the number of permits issued. Permit fees would be determined based on the recovery of NPS costs incurred in managing ORV use. Only annual permits would be available under this alternative, but these would be valid for 12 months from date of purchase so they could extend over the length of a season. To obtain the permit, ORV owners would be required to complete a short education program in person or online and pass a basic knowledge test demonstrating their understanding of the rules and regulations governing ORV use at the Seashore, beach-driving safety, and resource closure requirements. Following completion of the test, owners would need to sign for their permits to acknowledge that they understand the rules and that all drivers of the permitted vehicles will abide by the rules and regulations governing ORV use at the Seashore. A violation of the rules and regulations by the owner or driver of an ORV could result in revocation of the vehicle permit, and the owner/permittee would not be allowed to obtain another permit for any vehicle for a specified period of time.

Every five years the NPS would conduct a systematic review of the ORV and species management measures identified in this alternative as being subject to periodic review. This could result in changes to those management actions in order to improve effectiveness.

Designated routes and areas under alternative C are shown on figure 2 and described in table 7. Details of the management actions under this alternative are described in table 8 and species management strategies are described in table 10.

**ALTERNATIVE D: INCREASED PREDICTABILITY AND SIMPLIFIED MANAGEMENT**

This alternative is designed to provide visitors to the Seashore with the maximum amount of predictability regarding routes available for ORV use and vehicle-free areas for pedestrian use, which means establishing year-round ORV routes and vehicle-free areas. Under this alternative, ORV routes would be determined by identifying areas that historically do not support sensitive resources and areas of lower visitor use. These areas would be designated as ORV routes year-round. Areas of historically high resource sensitivity or high visitor use would not be designated as ORV routes. The establishment of ORV routes and vehicle-free areas on a year-round (rather than seasonal) basis would provide the public and the Seashore with a simplified management approach that would increase predictability and reduce confusion about what and when areas are available for ORV use, and reduce the need for staff resources on the beach. Because of the relative simplicity of the elements of this alternative, implementation would require a lower level of Seashore staff and resources than other action alternatives and would maximize the efficiency of Seashore operations.

Year-round vehicle-free areas would include lifeguarded beaches and the areas in front of villages, as well as designated SMAs. These vehicle-free areas would provide for visitor safety during periods of high visitation, particularly in the summer months, and would also provide a vehicle-free experience for visitors during the off-season. Soundside access would continue as currently provided under the no-action alternatives. Vehicle-free areas would also be established year-round at Cape Point and the spits to provide a simplified approach to sensitive species management for Seashore operations, maximizing contiguous protected areas and eliminating seasonal changes in designated ORV routes and the demands associated with enforcing those changes. Other uses would still be allowed in these vehicle-free areas outside any identified resource closures or SMAs. All SMAs would be managed using the ML1 strategy, which would involve larger and longer species protection buffers and would not allow pedestrian access once prenesting closures are established. Pedestrian access to these areas would be allowed once breeding activities are completed.

ORV routes under this alternative would still be subject to temporary resource closures established when protected species breeding behavior warrants and/or if new habitat is created. In addition to the breeding season measures, resource closures within some vehicle-free areas would be established, based on an annual nonbreeding habitat assessment conducted after the breeding season, to provide areas of nonbreeding shorebird habitat while still allowing a pedestrian or pedestrian/ORV access corridor in areas designated by the NPS (common to all alternatives).

To facilitate access to designated ORV routes, existing ORV ramps would be improved, reconfigured, and/or supplemented by new ramps at 62 and 64 (Note: All action alternatives involve relocating ramp 2 and building a new ramp at 32.5). No new or expanded parking areas would be provided under alternative D. Designated ORV routes would be open to ORV use 24 hours a day from November 16 through April 30. From May 1 through November 15, all potential sea turtle nesting habitat (ocean intertidal zone, ocean backshore, and dunes) would be closed to non-essential ORV use from 7:00 p.m. to 7:00 a.m. to provide for sea turtle protection and allow enforcement staff to concentrate their resources during the daytime hours.

ORV safety closures would not be designated; ORV users would drive at their own risk and would be expected to rely on their knowledge of beach driving to determine if an area is safe to access based on their assessment of current conditions.

Alternative D would not include a carrying-capacity requirement, but would limit vehicles to a one-vehicle-deep parking configuration so that areas would not become overcrowded such that a safety concern would occur.

Alternative D would include a simple vehicle permit system, with no limit on the number of permits issued. Permit fees would be based on the recovery of NPS costs incurred in managing ORV use, but the fee should be lower than fees under alternatives C, E, or F due to the decreased management costs under this alternative. Only annual (based on the calendar year, as opposed to a 12-month period) permits would be available under this alternative. To obtain a permit, ORV drivers would be required to read the rules and regulations governing ORV use at the Seashore, including beach-driving safety and resource closure requirements. Owners would need to sign for their permit to acknowledge that they understand the rules and that all drivers of the permitted vehicle will abide by the rules and regulations governing ORV use at the Seashore. Special consideration would be paid to providing beach safety information because of the lack of safety closures under this alternative. A violation of the rules and regulations by the owner or driver of the ORV could result in revocation of the vehicle permit, and the owner/permittee would not be allowed to obtain another permit for any vehicle for a specified period of time.

Every five years the NPS would conduct a systematic review of the species management measures identified in this alternative as being subject to periodic review. This could result in changes to those management actions in order to improve effectiveness.

Designated routes and areas under alternative D are shown on figure 2 and described in table 7. Details of the management actions under this alternative are described in table 8 and species management strategies are described in table 10.

#### **ALTERNATIVE E: VARIABLE ACCESS AND MAXIMUM MANAGEMENT**

This alternative is designed to provide visitors to the Seashore with a wide variety of access opportunities for both ORV and pedestrian users, including to the spits and points, but often with controls or restrictions in place to limit impacts on sensitive resources. During the shorebird breeding season, some ORV routes may be kept open to use for longer periods of time by providing ORV pass-through zones at some spits and points and by improving interdunal road and ramp access. More pedestrian access would be provided through substantial additions to parking capacity at various key locations that lend themselves to walking on the beach. Vehicle-free areas would be provided during all seasons for non-ORV users to experience the Seashore without the presence of vehicles. Like the other action alternatives, this alternative would manage ORV use by identifying areas that historically do not support sensitive resources and areas of lower visitor use. Most of these areas would be designated as ORV routes year-round. Areas of high resource sensitivity and high visitor use would either be designated as seasonal ORV routes, with restrictions based on seasonal resource and visitor use, or as year-round vehicle-free areas. In addition, the SMAs would be reopened to ORV use approximately six weeks earlier than under alternative C (September 1 versus October 15).

During the shorebird breeding season, ORV pass-through zones would be designated at Bodie Island Spit, Cape Point, and South Point. The pass-through zones would use standard resource protection buffers and would not allow pedestrians, pets, ORV stopping, parking, or disembarking of passengers. These pass-through zones would be established to provide an increased possibility of access during the prenesting and incubation periods only, and would be subject to resource closures. Once through the pass-through zone, recreation would be allowed outside any existing resource closures. Both Bodie Island Spit and South Point would have pedestrian-only areas, when conditions allow, extending access beyond the end of the ORV route. When unfledged chicks are present, the probability of being able to provide this access would decrease. Therefore, in addition to the pass-through zones, the Seashore would promote the use of water taxis as alternative transportation to Bodie Island Spit and South Point, subject to designated landing zones and resource closures. Alternative E also involves the development of an interdunal pedestrian trail on Bodie Island. The trail would begin at a new parking area near ramp 4 and would provide access to the inlet. This new trail would also be subject to resource protection closures.

The variety of access methods possible under alternative E, based on the establishment of ORV routes, seasonal vehicle-free areas, designation of ORV pass-through zones, and the promotion of water taxi service to designated points and spits, would provide the public with ORV and pedestrian access to a greater number of areas within the Seashore, even during portions of the shorebird breeding season. However, this alternative would afford less predictability than alternatives C and D regarding areas available for use and would require a greater amount of oversight and management. Implementation would perhaps be difficult for the public to understand and would require more Seashore staff and resources than the other alternatives.

Areas that would be seasonally designated vehicle free would include the areas in front of villages, except Frisco and Hatteras, and most of the SMAs. The ORV open season in front of the villages would be defined as November 1 to March 31 and in most SMAs from September 1 through March 14 (when a resource closure is not limiting access), with ORV access (via a pass-through zone) to Bodie Island Spit, Cape Point, and South Point from March 15 through August 31 via a pass-through zone, subject to resource closures. Soundside access would remain open at currently designated boat launch areas, on Hatteras Inlet Spit from the Pole Road to Cable Crossing and the Spur Road, and on Ocracoke Island soundside areas where commercial fishing access is currently allowed. Under this alternative, motorcycles would be allowed on all routes and areas open to ORVs on the soundside.

The remaining soundside access points would be closed to ORV use and small parking areas would be constructed to provide pedestrian access to the water. Signage/posts would be installed at the parking areas and boat launch areas to prevent damage to vegetation and other soundside resources.

ORV routes under this alternative would still be subject to temporary resource closures established when protected-species breeding behavior warrants and/or if new habitat is created. In addition to the breeding-season measures, resource closures and/or vehicle-free areas would be established, based on an annual nonbreeding habitat assessment conducted after the breeding season, to provide areas of nonbreeding shorebird habitat with reduced human disturbance while still allowing a pedestrian or pedestrian/ORV access corridor in areas designated by the NPS (common to all alternatives).

To facilitate access to ORV routes, this alternative would extend the existing interdunal road west of ramp 45 all the way to ramp 49, construct two new ramps (47 and 48), and build two new ramps at 62 and 64. (Note: All action alternatives involve relocating ramp 2 and building a new ramp at 32.5). A new ramp would be established at either 24 or 26, along with a new parking area at the selected location. Designated ORV routes would be open to ORV use 24 hours a day from November 16 through April 30. From May 1 through September 15, all potential sea turtle nesting habitat (ocean intertidal zone, ocean backshore, and dunes) would be closed to non-essential ORV use from 10:00 p.m. to 6:00 a.m. to provide for sea turtle protection and allow enforcement staff to concentrate their resources during the daytime hours. From May 1 through September 15, a limited number of ORV users would be permitted to park and stay overnight at selected spits and points, under the terms and conditions of a special use permit, when such areas are not otherwise closed to protect sensitive resources. From September 16 through November 15, ORV routes with no or a low density of turtle nests remaining (as determined by the NPS) would be open between 10:00 p.m. and 6:00 a.m., subject to the terms and conditions of a required permit (see table 8 for details). This alternative also involves the addition of parking spaces at several ramp locations.

ORV safety closures could be designated as conditions warrant and would be evaluated for reopening by NPS law enforcement staff on a weekly basis. ORV safety closures would be applicable only to ORV access; pedestrian and commercial fishing access would generally be maintained through ORV safety closures. For village beaches that are open to ORV use during the winter season, the village beaches must be at least 20 meters wide from the toe of the dune seaward to the mean high tide line in order to be open to ORV use.

Alternative E would include a carrying-capacity requirement for all areas based on a physical space requirement of one vehicle per 20 linear feet for Bodie and Hatteras Island Districts, except 400 vehicles would be allowed within a 1-mile area centered on Cape Point, and one vehicle per 30 linear feet for the Ocracoke Island District. The carrying capacity would be implemented whenever overcrowding could cause safety concerns, such as at peak use periods during major summer holidays and weekends. The allowable number of vehicles in each area would be determined by the space requirements and the beachfront length of the area.

Alternative E would include an ORV permit system, with no limit on the number of permits issued. Permit fees would be determined based on the recovery of NPS costs incurred in managing ORV use. Expected permit fees would be higher under this alternative due to the intense level of management required for implementation. Both annual and weekly permits would be available under this alternative. To obtain a permit, ORV owners would be required to complete a short education program in person or online and pass a basic knowledge test demonstrating their understanding of the rules and regulations governing ORV use at the Seashore, beach-driving safety, and resource-closure requirements. Following completion of the test, owners would need to sign for their permit to acknowledge that they understand the rules and that all drivers of the permitted vehicle will abide by the rules and regulations governing ORV use at the Seashore. A violation of the rules and regulations by the owner or driver of the ORV could result in revocation of the vehicle permit, and the owner/permittee would not be allowed to obtain another permit for any vehicle for a specified period of time. The park-and-stay provision would be managed under a separate special use permit. Alternative E would also include a self-contained vehicle (SCV) camping opportunity from November 1 to March 31 at three NPS campgrounds (one in each district), with a separate permit requirement and use limits.

Every five years the NPS would conduct a systematic review of the ORV and species management measures identified in this alternative as being subject to periodic review. This could result in changes to those management actions in order to improve effectiveness.

Designated routes and areas under alternative E are shown on figure 2 and described in table 7. Details of the management actions under this alternative are described in table 8 and species management strategies are described in table 10.

#### **ALTERNATIVE F: NPS PREFERRED ALTERNATIVE**

In December 2007, the Department of the Interior established a negotiated rulemaking advisory committee (Committee) to assist the NPS in the development of an ORV regulation for the Seashore. The Committee met 11 times from January 2007 through February 2009, and conducted numerous subcommittee and work group meetings and conference calls. The Committee discussed and explored options for the full spectrum of ORV management issues covered in this plan/EIS. As a result of these discussions, the NPS considered a variety of concepts and measures that either originated from Committee members or were discussed during Committee, subcommittee, or work group sessions. Although the Committee as a whole did not reach a consensus on a recommended alternative, in creating this action alternative the NPS has made management judgments as to which combination of concepts and measures would make an effective overall ORV management strategy. The NPS has also included under alternative E some ORV management approaches identified by the Committee that would require more intensive management (such as park-and-stay and SCV camping), in keeping with the maximum management theme of that alternative.

After reviewing public and agency comments, the NPS revised alternative F by adopting some of the simpler approaches from the other alternatives, e.g., instead of SMAs, using standard buffers with prenesting and nonbreeding closures; simpler and easier to understand hours for night-driving restrictions;

and using more consistent seasonal closure dates among the villages. Also in response to public and agency comments, the amount of construction was decreased and pedestrian access increased. The bypass provision and criteria from alternative A was incorporated in alternative F to mitigate effects of sea turtle closures that could block fall ORV access to Cape Point. Designation of ORV routes was adjusted to provide balance between ORV areas and vehicle-free areas.

This alternative is designed to provide visitors to the Seashore with a wide variety of access opportunities for both ORV and pedestrian users, including access to the spits and points, but often with controls or restrictions in place to limit impacts on sensitive resources. This means that some areas may be kept open to ORV users for longer periods of time by reopening some ORV corridors at the spits and points sooner after shorebird breeding activity is completed than in alternatives C or E, and by improving interdunal road and ORV ramp access. Pedestrian access would be enhanced by providing increased parking capacity at various points of access to vehicle-free areas. Such areas would be provided during all seasons so non-ORV users can experience the Seashore without the presence of vehicles. Like the other action alternatives, this alternative would manage ORV use by identifying areas that historically do not support sensitive resources and areas of lower visitor use. Some of these areas would be designated as ORV routes year-round. Areas of high resource sensitivity and high visitor use would generally be designated as vehicle-free areas year-round or as seasonal ORV routes, with restrictions based on seasonal resource and visitor use.

The year-round designation of vehicle-free areas and ORV routes, in conjunction with the species management strategies described in table 10-1, would provide for species protection during both the breeding season and the nonbreeding season. SMAs would not be designated under this alternative and one set of standard buffers, similar to the ML2 buffers in the other action alternatives, would be used. During the shorebird breeding season, pedestrian shoreline access along ocean and inlet shorelines below the high-tide line would be permitted in front of (i.e., seaward of) prenesting areas until breeding activity is observed, then standard buffers for breeding activity would apply. The NPS retains discretion at all times to enforce more proactive closures or take other measures, if considered necessary, consistent with its obligations under the law. Prenesting areas would generally be closed March 15 through July 31 (or August 15 if black skimmers are present), or until two weeks after all chicks have fledged and breeding activity has ceased, whichever comes later. For all species closures, including prenesting closures, the NPS would not reduce buffers to accommodate an ORV corridor or ORV ramp access.

Bodie Island Spit would be designated as a seasonal ORV route from September 15 through March 14 and would be vehicle free from March 15 through September 14. Like alternative E, alternative F also involves the development of an interdunal pedestrian trail on Bodie Island. The trail would begin at a new parking area near ramp 4 and would provide access to the inlet. This new trail would also be subject to resource-protection closures. Year-round ORV routes would be designated at Cape Point and South Point, with 35-meter-wide (115-foot-wide) ORV corridors during the breeding season. Standard resource-protection buffers would apply to these ORV corridors. When nests occur near the ORV corridor or unfledged chicks are present, the probability of being able to provide this access would decrease. The provision and criteria described in alternative A for creation of short-term bypasses would be incorporated in alternative F only for sea turtle nests and only between ramp 44 and Cape Point. Alternative F would include the construction of a short seasonal ORV route to provide pedestrian access to the sound on Ocracoke Island. In addition, the NPS would consider applications for commercial use authorizations to offer beach and water shuttle services and would apply for funding to conduct an alternative transportation study to evaluate the feasibility of alternative forms of transportation to popular sites, such as inlets and Cape Point.

The variety of access methods possible under alternative F, based on the establishment of year-round and seasonal ORV routes and vehicle-free areas, and increased interdunal roads and parking to support access,

would provide the public with ORV and pedestrian access to a greater number of areas within the Seashore. This alternative would afford less predictability than alternative C or D, but more predictability than alternative E, regarding areas available for use, and it would require a comparable level of oversight and management to alternative E.

Areas that would be seasonally designated as vehicle free would include the areas in front of Ocracoke Campground and villages, except for Rodanthe north of the pier and Buxton, which would be vehicle free year-round. The dates for ORV use in front of the seasonally designated villages and Ocracoke Campground would be November 1 to March 31 when visitation and rental occupancy is lowest. These areas would be vehicle free April 1 to October 31 when visitation and rental occupancy is highest. When these beaches are open to ORV use, a safety closure would be implemented on portions of the beach that are not consistently at least 20 meters (66 feet) wide during normal high tides.

To facilitate access to ORV routes, this alternative would add new ramp 25.5 approximately 2.5 miles south of ramp 23, relocate ramp 59 to 59.5, and add a new ramp 63 across from Scrag Cedar Road. (Note: All action alternatives involve relocating ramp 2 and building a new ramp at 32.5). New interdunal roads would facilitate access to locations that have either seasonal or year-round restrictions on ORV use. Locations for interdunal roads would include: inland of South Beach from ramp 45 to ramp 49, with one new ramp at 47.5 and on Hatteras Inlet Spit extending from the intersection of Pole and Spur Roads southwest toward the inlet, stopping at least 100 meters from the inlet. Existing soundside access points would remain open, with better maintenance than currently occurs. Signage/posts would be installed at the soundside parking areas and boat launch areas to prevent damage to vegetation and other soundside resources. This alternative also involves the addition of new parking areas with associated foot trails or boardwalks to facilitate pedestrian access at a number of locations.

ORV routes and vehicle-free areas under this alternative would still be subject to temporary resource closures established when protected-species breeding behavior warrants and/or if new habitat is created. Outside the breeding season, vehicle-free areas throughout the Seashore would provide relatively less-disturbed foraging, resting, and roosting habitat for migrating and wintering birds. These areas would be open to pedestrians for recreational use. In addition, resource closures at spits and points would also be established, based on an annual nonbreeding habitat assessment conducted after the breeding season, to provide areas of nonbreeding shorebird habitat with reduced human disturbance.

Designated ORV routes would be open to ORV use 24 hours a day from November 16 through April 30. From May 1 through November 15, all potential sea turtle nesting habitat (ocean intertidal zone, ocean backshore, and dunes) would be closed to non-essential ORV use from 9:00 p.m. until 7:00 a.m. to provide for sea turtle protection and allow enforcement staff to concentrate their resources during the daytime hours; however, from September 16 through November 15 selected ORV routes with no turtle nests remaining (as determined by the NPS) would reopen to night driving, subject to the terms and conditions established under the ORV permit.

ORV safety closures could be designated as conditions warrant and would be evaluated for reopening by NPS law enforcement staff on a weekly basis. ORV safety closures would be applicable only to ORV access; pedestrian and commercial fishing access would generally be maintained through safety closures. Alternative F provides specific guidelines for establishing and removing safety closures. Additional ORV-driving requirements would be implemented to provide for increased pedestrian safety in all areas open to ORV use, including the village beaches when open to ORV use. Under the carrying capacity requirement for alternative F, the maximum number of vehicles allowed on any particular ORV route during peak use periods would be the linear distance of the route divided by 6 meters (20 feet) per vehicle (i.e., the equivalent of 260 vehicles per mile). In addition, parking within ORV routes would be allowed,

but restricted to one vehicle deep. These measures would reduce safety concerns associated with overcrowding, such as at peak use periods during major summer holidays and weekends.

Alternative F would include an ORV permit system, with no limit on the number of permits issued. Permit fees would be determined based on the recovery of NPS costs incurred in implementing the ORV management plan that are not already covered by the Seashore's base operating funds. Expected permit fees would be similar to alternative E due to the level of management required for implementation. Both annual and 7-day permits would be available under this alternative. To obtain a permit, ORV owners would be required to complete a short education program in person at an NPS facility. Vehicle owners would need to sign for their permit to acknowledge that they understand the rules and that all drivers of the permitted vehicle will abide by the rules and regulations governing ORV use at the Seashore. A violation of the rules and regulations by the owner or driver of the ORV could result in revocation of the vehicle permit, and the owner/permittee would not be allowed to obtain another permit for any vehicle for a specified period of time. In addition to the mandatory education program for ORV users, the NPS would establish a voluntary resource-education program targeted toward non-ORV beach users.

Every five years the NPS would conduct a systematic review of the species management measures identified in this alternative as being subject to periodic review. This could result in changes to those management actions in order to improve effectiveness.

Designated ORV routes under alternative F are shown on figure 2 and described in table 7-1. Details of the management actions under this alternative are described in table 8 and species management strategies are described in table 10-1.

## **HOW ALTERNATIVES MEET OBJECTIVES**

As stated in chapter 1 of this document, all action alternatives selected for analysis must meet all objectives to a large degree. The action alternatives must also address the stated purpose of taking action and resolve the need for action; therefore, the alternatives were individually assessed in light of how well they would meet the objectives for this plan/EIS, which are stated in chapter 1 of this document. Alternatives that did not meet the objectives were not analyzed further (see the "Alternative Elements Considered but Dismissed from Further Consideration" section in this chapter).

Table 12 compares how each of the alternatives described in this chapter would meet the plan objectives. Chapter 4 of this document describes the effects of each alternative on each impact topic. These impacts are summarized in table 13. Tables 12 and 13 are included at the end of this chapter.

## **ALTERNATIVE ELEMENTS CONSIDERED BUT DISMISSED FROM FURTHER CONSIDERATION**

### **USE AREAS, ORV MANAGEMENT, AND VISITOR USE**

#### **Modify the ORV Management Plan in Accordance with Plans Proposed by Groups Outside the NPS**

During the public comment period for the draft plan/EIS, alternative plans for the management of ORVs and wildlife at the Seashore were submitted. Many of the elements in these proposals are already included in the range of alternatives considered, or have been incorporated into the revised alternative F (NPS preferred alternative). Those elements that are not included were considered but dismissed for the reasons discussed below under the headings: Implement Additional Vehicle Requirements, Additional

Requirements for Permit Holders, Alternative Methods for Determining ORV Carrying Capacity, Allow for a Greater Level of Night Driving at the Seashore, Provide an ORV Pass-through Corridor through All Species Closures/Buffers, Criteria for the Designation of SMAs, Relocate Bird and Turtle Nests, Modify the Turtle Program, Implement a Volunteer Program to Assist with Species Protection, Create an Oversight Committee with External Experts and Scientists, Create New Habitat, and Give Special Consideration only to Flora and Fauna Listed as Threatened or Endangered.

### **Consider Pea Island National Wildlife Refuge when Considering Use Areas**

Many commenters suggested that Pea Island NWR (refuge) should be considered when developing this plan/EIS. Suggestions included considering the refuge as a vehicle-free area, and conversely, as a potential area where ORVs could be used where there is not a resource conflict. Commenters felt that the refuge should be considered a part of the baseline for analysis, and should be considered when providing appropriate visitor use. Although the 5,880-acre Pea Island NWR is located at the northern end of Hatteras Island, and is within the boundary of the Seashore, the refuge is administered by the USFWS. The Seashore's 1978 draft interim ORV management plan affirmed that the refuge manager has management responsibility for posting closures on beaches within the refuge as he or she may find necessary to implement the regulations of the USFWS. The NPS recognizes that approximately 12.1 miles of beach within the refuge has been closed to ORVs for a number of years and at present provides an opportunity for visitors to the north end of Hatteras Island to walk on the beach in the absence of vehicles; however, because the refuge is not administered by the NPS, the Seashore cannot direct the management of visitor use at the refuge. The USFWS is responsible for making decisions about ORV and pedestrian access and has done so under a public planning process in the Pea Island National Wildlife Refuge Comprehensive Conservation Plan (USFWS 2006b), as mandated by the *National Wildlife Refuge Improvement Act of 1997*. Through this process, the USFWS has determined that ORV use would not be appropriate or compatible with the mission of the refuge.

NPS also recognizes that there are times and locations on Nags Head and Cape Lookout National Seashore beaches, where ORVs may and may not be driven, providing additional opportunity for recreation with and without vehicles. Under the *Organic Act*, the NPS is responsible for managing activities in the Seashore to conserve the natural resources unimpaired on NPS-managed lands within the Seashore, which includes protecting the wildlife and its habitat. Similarly, under the Seashore's enabling legislation, NPS is mandated to preserve the unique flora and fauna and physiographic conditions. The presence of a species outside the Seashore does not mitigate, eliminate, or affect the authority and responsibility of the NPS under both the *Organic Act* and the Seashore enabling legislation to preserve unimpaired the Seashore populations of wildlife.

### **Prohibit the Use of Off-Road Vehicles**

Prohibition of ORV use at the Seashore would not meet the purpose, need, and objectives of this plan/EIS. The purpose of this plan is to “develop regulations and procedures that carefully manage ORV use/access in the Seashore to protect and preserve natural and cultural resources and natural processes, provide a variety of visitor use experiences while minimizing conflicts among various users, and promote the safety of all visitors...” ORV use, if effectively managed, provides convenient access for many appropriate visitor activities at some popular beach sites including, for example, activities that use vehicles to transport substantial amounts of gear for the activity. Prohibition, rather than management, of ORV use could substantially diminish such visitor experience opportunities. Therefore prohibition of all ORV use would not meet the plan need.

In addition to not meeting the purpose, need, and objectives of this plan/EIS, ORV use is a historical use at the Seashore that has been accounted for in Seashore planning documents. Management goals related to ORV use are included in the Seashore's General Management Plan, which states, “Selected beaches will

continue to be open for ORV recreational driving and in conjunction with surf fishing in accordance with the existing use restrictions” (NPS 1984). Providing for this use would occur in the context of the overall planning objective of preserving the cultural resources and the flora, fauna, and natural physiographic conditions, while providing for appropriate recreational use and public access to the oceanside and soundside shores in a manner that will minimize visitor use conflict, enhance visitor safety, and preserve Seashore resources. ORV use preceded the establishment of the Seashore and management of this use, rather than prohibition, continues to be the intent of the NPS. The NPS acknowledges that if it does not promulgate a special regulation to authorize ORV use, then ORV use would, in fact, be prohibited at the Seashore; however, because a complete prohibition of ORV use does not meet the purpose, need, and objectives of this plan/EIS and because ORV use is a use that is accounted for in Seashore plans and policies, elimination of all ORV use at the Seashore was not carried forward for further analysis.

### **Changes in Infrastructure and Regulations of Other Jurisdictions**

Commenters suggested elements that would involve jurisdictions outside the NPS, including:

- Provide NPS parking and beach access points throughout Dare County villages.
- Lower the speed limit on NC-12 between villages to 45 mph during peak use times to reduce the danger from vehicles with aired-down tires.
- Limit the use of bright lighting in oceanfront houses.
- Create a sound ordinance.
- Create guidelines for oceanfront structures, such as setbacks from the high-tide mark and rebuilding guidelines, to address damage to existing oceanfront structures.

These suggestions would require action by the county or state. Lowering the speed limit would require a change in current state regulations. The county would be responsible for changing building codes or adding more parking and access points. Creating sound or turtle friendly lighting ordinances or occupancy restrictions for rental homes would require action of the respective counties. The NPS does not have the authority to require these jurisdictions to undertake such action. However, the NPS has worked with the communities within the Seashore on many issues, including those related to ORV management, and under all alternatives would continue to work cooperatively to encourage actions such as turtle-friendly lighting and education. Although the NPS cannot require Dare County to provide more parking or beach access, some of the alternatives evaluated in this plan/EIS address additional parking areas on Seashore land.

### **Implement Additional Vehicle Requirements**

During public comment on the draft plan/EIS, commenters recommended additional vehicle requirements such as requiring vehicles to be oil leak free, permitting only electric vehicles, and requiring that license plates be displayed properly. The Seashore does not have the capability to efficiently inspect each vehicle that enters the beach to determine if it is leaking oil. Individual vehicle inspections for leaking fluids could cause substantial traffic backups, which would adversely affect visitor experience and safety. However, all vehicles operated in the Seashore must comply with state inspection requirements, which include regulations on leaking fluids. If the NPS were to observe a vehicle leaking oil, it would be removed from the beach. The NPS is not proposing to allow only electric vehicles in the Seashore due to the limited availability of these vehicles to the general public. Obstruction of the rear license plate is a violation of North Carolina law, which is enforced by NPS law enforcement staff under 36 CFR 4.2(b). In developing the details of the ORV permit program, the Seashore would consider whether this violation would be a basis for permit revocation.

### **Provide All-Terrain Vehicle/Utility Terrain Vehicle Access and Remove the Helmet Requirement**

Commenters suggested that ATVs and utility terrain vehicles (UTVs) should be allowed on the beach and that ATV users should not be required to use helmets. The NPS only allows street-legal vehicles on the beach under the North Carolina Motor Vehicle Code, which does not include ATVs or UTVs.

Alternatives in this plan/EIS do not include changing the requirement for street-legal vehicles. The Seashore considers ATV and UTV use at the Seashore to be incompatible with visitor use and resource protection goals and objectives due to the damage they could cause. Further, street-legal vehicles are used for transportation, but the majority of ATVs and UTVs are used primarily for recreational or utility purposes, although they may secondarily serve a transportation function. Since ATVs and UTVs would not be permitted, the issue of requiring helmets is not applicable.

### **Assign Permits to Users Instead of Vehicles**

For the alternatives that include a permit system, permits would be assigned to a particular vehicle through issuance to the registered owners of vehicles. A permit sticker would then be affixed to the vehicle, where it would be easily visible by law enforcement personnel. Another option of assigning permits to the person only, not the vehicle, was considered, but eliminated. Verifying that people have permits that are movable between multiple vehicles would require substantially more effort by law enforcement staff, who would have to stop each driver visitor and ask to see their permit. Therefore, to assist in enforcing the permit system, permits are assigned to the registered owners and affixed to the vehicles under all alternatives.

### **Require a Permit for All Users of the Seashore**

The idea of an entrance or admission fee for the Seashore was discussed thoroughly during the negotiated rulemaking process, and was dismissed primarily due to administrative and financial obstacles. The establishment of an entrance fee would require the NPS to install manned entrance gates in the Seashore to collect visitor fees. However, there are thousands of local residents who have to travel through the Seashore to gain access to their property. The logistics of collecting entrance fees from all visitors would result in delays at entrances and would impede efficient travel along NC-12.

In addition, parking and access fees are managed under the *Federal Lands Recreation Enhancement Act* (FLREA), which does not provide for a cost recovery program. Therefore, the Seashore would be able to retain only a portion of the entrance or parking fees collected and could not use those funds to support key functions associated with an ORV management program, such as law enforcement, maintenance of routes or parking lots, or resource management. As a result, the collection of admission and parking fees was not carried forward for further analysis.

### **Provide Separate Permits for Different Areas of the Seashore as a Means of Limiting Congestion**

The ORV permit system is an enforcement and education tool to reduce adverse impacts to park resources and visitor experience. It is not intended to limit the number of ORVs on Seashore beaches. During internal and public scoping as well as the negotiated rulemaking process, the NPS considered various methods for establishing an ORV permit system. A common theme among the alternatives for ORV permits was that fees should be kept reasonable so that all visitors, regardless of income level, would be able to afford to purchase an ORV permit. The most logical method of implementing an ORV permit system would be to use the special park uses authority under 16 USC 3a which would allow the Seashore to recover the cost of implementing the ORV management program. A permit system that required a

different permit for different locations in the Seashore would be complex to implement, resulting in increases in NPS management costs. Such costs would ultimately be passed along to ORV users because the permit fees would be based on cost recovery. Therefore, more complex permitting systems were considered but not carried forward for analysis. As a result, the concept of establishing vehicle limits in certain areas through an ORV permit system was not carried forward for further analysis.

### **Additional Requirements for Permit Holders**

During public comment on the draft plan/EIS, commenters recommended a range of requirements that could be included in a permit system such as having permit holders report turtle crawl activity. Although the Seashore encourages the public to report certain species activities, including turtle crawls, *requiring* the public to report turtle crawls would not be appropriate as part of an ORV permit program and was dismissed from further analysis. However, suggestions made for various educational components, such as watching an educational video, are included in the range of alternatives.

### **Provide Night Parking at the End of Access Ramps on the Beach Side and Along the Sandy Road Behind the Dunes at Cape Point and the Spits**

Night parking (but not camping) for pedestrian beach access would be allowed at roadside parking areas identified on the maps for alternative F. Allowing vehicles to park overnight on interdunal roads or ORV ramps immediately adjacent to resource sensitive locations would be difficult to patrol and enforce. Additionally, it could place an unrealistic expectation on visitors in such locations to strictly comply with the applicable resource protection restrictions. The NPS does not have the resources to patrol the entire Seashore at night to enforce compliance. The placement of more parked vehicles on ORV routes adjacent to the beach at night would potentially result in additional compliance problems, and was not carried forward for further analysis.

### **Locate ORV Routes Behind the Dunes, Away from Pedestrian Users**

Routes behind the dunes would be more damaging to the environment in some cases because the land there is not hard, bare beach sand but instead is loose sand, and the area contains vegetation and other wildlife. Additionally, interdunal roads would not allow the same degree of access that designated ORV routes would provide to visitors that use ORVs for access to recreational activities. Some interdunal roads would be provided to allow for ORV access around designated vehicle-free areas. As a result, locating ORV routes behind dunes as a general practice was not carried forward for further analysis.

### **Alternative Methods for Determining ORV Carrying Capacity**

During public comment on the draft plan/EIS, commenters provided a range of suggestions for determining the ORV carrying capacity at the Seashore. This includes extending carrying capacity limits to all areas of the Seashore, allowing vehicles to stack more than one deep, implementing limits on pedestrian use, and increasing or decreasing the proposed vehicle limits. Overall, the NPS established carrying capacity limitations primarily as a visitor safety mechanism to reduce the potential for vehicle-vehicle and pedestrian-vehicle conflicts that can occur in areas where vehicles and pedestrians coexist. The NPS considered various options for determining carrying capacity limits which are included in the range of the alternatives in this plan/EIS. For more information please see “Appendix C: Concern Response Report” (response to Concern ID 24129).

### **Use a Different Term for “Requirement” in Law Enforcement Text**

Commenters suggested using the words “courtesy,” “guidelines,” or “rule” instead of “requirements.” Where the word “requirements” is used in an alternative, it implies a level of regulatory enforcement authority. In these areas, changing the word to “guidelines” or “courtesy” would not imply enforcement capability; therefore, this suggestion was not carried forward in the alternatives.

### **Provide Around-the-Clock Enforcement**

Commenters suggested that around-the-clock enforcement would ensure resource protection. The Seashore has no source of funding capable of supporting around-the-clock enforcement in all areas at all times. This suggested level of enforcement is not the norm for any national seashore. The action alternatives provide for increased outreach and education to help improve voluntary compliance, but around-the-clock enforcement would not be feasible and was therefore not included in any alternatives.

### **Designate a “Backcountry Zone” Where Pedestrians Can Walk**

Designation of a backcountry zone is not within the scope of this project. However, the Seashore will address park management zones in the revision of the General Management Plan (GMP) for the Seashore.

### **Establish Two Marked Travel Paths on the Beach**

Marking travel lanes in ORV routes along the length of the Seashore would not be possible nor desirable because of the visual impact. However, alternative F requires that two-way traffic remain unimpeded within ORV routes and also provides the Seashore with the authority to close down a section of beach if two-way traffic is impeded.

### **Construct an “Access Trail” to Hatteras Spit**

Over the past several years, the Seashore has provided ORV access to the back side of Hatteras spit whenever it would not result in human safety or resource impacts. Some of the sound shoreline area is very narrow; having a small strip of sand that is subject to flooding at high tide unless one drives on the vegetation. This includes wetland vegetation that bounds it on the land side. Because it is problematic to access the sound from Pole Road at other points, alternative F provides for ORV access to the sound behind the Coast Guard Station, at Cable Crossing and at Spur Road, and did not carry an access trail to Hatteras Spit forward for further analysis.

### **Add a Public Soundside Beach on Ocracoke**

NPS believes that the suggestion to provide a soundside beach on Ocracoke has merit. However, it is outside the scope of the ORV plan/EIS and was not included in the alternatives carried forward for further analysis. The NPS believes that it would be an appropriate topic for the Seashore’s upcoming GMP revision process.

### **Divide the Seashore by Different Recreational Uses**

The purpose of the plan is to develop regulations and procedures that carefully manage ORV use/access in the Seashore to protect and preserve natural and cultural resources and natural processes; to provide a variety of visitor use experiences while minimizing conflicts among various users; and to promote the safety of all visitors. While it is recognized that individuals who use ORVs do so for a variety of purposes or to pursue different recreational interests, developing a nuanced approach to designating ORV areas

based on the different individual interests would be extremely difficult and is beyond the scope of this plan. Therefore, this approach was not carried forward as an element of the alternatives evaluated. The NPS believes that the range of alternatives evaluated in this plan/EIS provide various ORV routes and vehicle-free areas, which offer visitors the opportunity to select the locations best suited for pursuing their respective interests, whether it be fishing, swimming, shell collecting, bird watching, or other uses.

### **Allow for a Greater Level of Night Driving at the Seashore**

During public comment on the draft plan/EIS, commenters requested that night driving only be restricted between May 27 and August 25, and requested that some level of nighttime access be maintained between these dates. NPS considered a range of dates for night driving from unrestricted night driving, 365 days per year in alternative A to the dates for nighttime restrictions in alternatives B – F. These dates were identified based on the sea turtle nesting season to reduce the chance for direct or indirect impacts to nesting sea turtles from ORV use. Since 2000, three nests were found prior to May 15 (two of which were leatherback nests) and four nests have been found after September 1. It is important to note that prior to 2008, nest patrols were conducted only from June 1 through August 31 (2001–2005), or May 15 through September 15 (2006 and 2007). Any nests laid outside of that timeframe had a greater likelihood of not being found, recorded, and protected by resource management staff.

Direct adverse impacts of nighttime driving were documented during the 2010 nesting season when an ORV driving on the beach at night – in violation of the consent decree – struck and killed a nesting female loggerhead turtle during the nighttime hours between June 23 and June 24. The turtle had crawled out of the ocean and attempted to lay a nest between ramps 70 and 72 on Ocracoke Island. The ORV hit the turtle and dragged her approximately 12 feet, causing fatal injuries. The turtle was found dead by NPS turtle patrol at 6:10 a.m. on June 24. This particular incident is the first documented time a nesting sea turtle has been killed by an ORV at the Seashore (NPS 2010b).

The NPS believes that nighttime restrictions from May 1 until November 15 provide the proper level of protection for sea turtles. Further, the NPS believes that providing exceptions to this would have unacceptable adverse impacts to sea turtles at the Seashore. For these reasons, the NPS did not specifically analyze a May 27 to August 25 nighttime driving restriction period.

### **No Restrictions on ORV Use**

Unrestricted ORV use at the Seashore would not meet the purpose, need, and objectives of this plan/EIS. The purpose of this plan/EIS is to “develop regulations and procedures that carefully manage ORV use/access in the Seashore to protect and preserve natural and cultural resources and natural processes, to provide a variety of visitor use experiences while minimizing conflicts among various users, and to promote the safety of all visitors.” Unrestricted ORV use would not provide for a variety of appropriate uses and, therefore, not meet the plan/EIS need. Also, the need of the plan/EIS, including providing consistent management of ORV use, would not be addressed. Unrestricted ORV use would not meet many of the plan/EIS objectives that relate to managing ORV use. For example, the following three Visitor Use and Experience objectives would not be met if unrestricted ORV use was allowed:

- Ensure that ORV operators are informed about the rules and regulations regarding ORV use at the Seashore.
- Manage ORV use to allow for a variety of visitor use experiences.
- Minimize conflicts between ORV use and other uses.

Therefore, because it would not meet the purpose, need, and objectives of this plan/EIS, unrestricted ORV use was not carried forward for further analysis.

## **SPECIES PROTECTION**

### **Implement an Escort Program**

During development of the Interim Strategy, some alternative elements were considered but not carried forward because they would be reevaluated in this plan/EIS. One of these elements was the implementation of an escort program, whereby vehicles would be escorted around resource closures by Seashore staff.

This program would be similar to the situation in 2005, where at Hatteras Inlet Spit, ORV traffic was permitted only in the ORV corridor once per hour in convoys escorted by bird monitors, to reduce the risk of mortality to an American oystercatcher brood and to reduce disturbance to an incubating plover nest. ORVs were permitted to park at the tip of the spit, west of the escort corridor. The spit was closed to recreation at night. Once the piping plover eggs hatched, Hatteras Inlet Spit was closed to ORV traffic until the chicks fledged.

This type of escort system was considered for this plan/EIS, but, as stated in the Interim Strategy, the escort system would be extremely labor intensive to initiate, and providing the staffing levels necessary to adequately implement an escort program would likely not be feasible. This was demonstrated during the 2005 season when the Seashore had to transfer personnel from other NPS units to implement the escort system. Due to the intensive staffing required for this effort, it was determined that this element would not meet the plan/EIS objectives related to Seashore operations.

### **Provide an ORV Pass-through Corridor through All Species Closures/Buffers**

During public comment on the draft plan/EIS, commenters recommended providing a corridor through all species resource closures and buffers. A buffer or resource closure is an area surrounding a sensitive resource, such as bird nests or chicks, which is closed to visitor access during critical life cycle stages to reduce human disturbance and the risk of mortality due to pedestrians and ORVs. Any passages, corridors, or pass-throughs that cut directly across/through a resource closure would essentially undermine the biological function of the closure and could render it compromised, perhaps even useless to the species it is meant to protect if all buffers include ORV corridors. Therefore, the element of including an ORV corridor in all buffers was not included in the range of alternatives, but a more limited concept of a pass-through was included in alternative E.

### **Criteria for the Designation of Species Management Areas**

During public comment on the draft plan/EIS, commenters recommended additional criteria for the designation of SMAs. Such criteria included areas of high quality habitat (even if there has not been recent breeding activity), how SMAs should be established and expanded, and the use of 10 years (rather than 5 years) of nesting history to designate these areas. The concept of including high quality habitat was incorporated in the range of alternatives by the use of prenesting surveys that would result in prenesting closures of suitable habitat. Although the SMA would not be designated based on the "high quality habitat" criteria, these areas would still be offered protection through the prenesting survey and closure. This would also apply to expanding SMAs; although the SMA itself would not expand habitat, outside the SMA would be protected through prenesting closures or breeding/nesting buffers. For these reasons, these elements were not carried forward for further analysis.

The use of 10 years, rather than 5 years, of nesting history to designate SMAs was not considered a reasonable alternative because so much potential nesting substrate is impacted and rearranged on an annual basis, especially during fall and winter storms. Since this area is frequently changing, it is believed that it is sufficient to use breeding and nesting location data from the five previous years in conjunction with an annual pre-season habitat assessment. Given how much annual change there is in suitable nesting substrates on barrier islands, 10 years of nesting/breeding data would very likely capture many sites that do not presently have sufficient potential to support breeding populations. As a result, the use of 10 years of nesting data was not carried forward for detailed analysis.

### **Move Hatched Chicks to Pea Island National Wildlife Refuge or Other Area**

Commenters suggested moving hatched bird chicks from the beach to other areas where they would be protected. This conflicts with NPS responsibilities under the ESA, MBTA, *Organic Act* (as described in the turtle hatcheries section below), and the NPS *Management Policies 2006*. Further, moving chicks is not feasible because until they fledge, chicks must remain with their parents for foraging and protection. Relocating chicks would not meet the plan/EIS objective of minimizing adverse impacts to threatened, endangered, and other protected species.

### **Provide Captive Rearing of Piping Plovers and Turtles**

Commenters suggested rearing endangered species in captivity. Wildlife managers use captive breeding/rearing of threatened or endangered species in the following circumstances: (1) to provide an opportunity to restore populations where direct translocation may risk the persistence of the donor population; or (2) as a last resort in cases where most or all of the entire remaining wild population are brought to a captive breeding facility with the goal of avoiding extinction and breeding enough individuals for eventual reintroduction into the wild (e.g., California condor) (Gilpin and Soulé 1986). The Kemp's ridley sea turtle hatchery at Padre Island National Seashore is an example of a last-resort captive rearing facility used to restore a population. None of these situations apply to piping plover or nesting loggerhead, leatherback, or green sea turtles at Cape Hatteras National Seashore, so this suggestion was not included in any of the alternatives. Furthermore, the revised Loggerhead Sea Turtle Recovery Plan (NMFS and USFWS 2008) recommends the use of the least manipulative method to protect nests and the discontinuance of the use of hatcheries as a nest management technique.

### **Relocate Bird and Turtle Nests**

Commenters suggested that the Seashore relocate bird or turtle nests to areas of the beach already closed to ORV use or relocate nests to smaller, more compact areas to facilitate management. These alternatives have been considered but are not carried forward, as discussed below.

**Birds.** Some species of birds, such as the burrowing owl, adapt well to nest relocation, but others do not. Birds that do not relocate well typically are those that demonstrate higher levels of nest abandonment. Nest abandonment by piping plovers and American oystercatchers is a documented source of nest failure at the Seashore. Therefore, relocating nests would likely result in increased nest abandonment and failure. In addition, moving nests into one area would not be feasible. Plovers and oystercatchers are solitary rather than colonial nesters (i.e., they nest away from others of their species). Plovers sometimes nest near tern colonies to benefit from the aggressive behavior of terns protecting their colonies; however, they typically do not nest with other plovers. Since the purpose of the strategy is species protection, and moving nests would reduce these species' ability to reproduce, moving nests was eliminated from further analysis.

**Turtles – Routinely Relocate Turtle Nests.** Turtles do not face the same nest-abandonment issues as those described for birds. Parental investment in the young ends with the laying and burying of eggs. However, the eggs, subsequent hatchlings, and overall species may face additional problems related to nest relocation. Studies indicate that the determination of the hatchling sex ratio depends on the temperature at which the eggs incubate. Changes in these temperatures due to moving eggs may result in changes to the sex ratio, which would have implications for the species as a whole.

Other hatchling characteristics can be altered by relocating nests as well. Sea turtles naturally distribute their nests both temporally (nest several times throughout the nesting season) and spatially (locate nests low or high on the beach and in different sections along the beach). This not only helps to avoid completely losing their reproductive effort in case environmental factors (such as storms, temperature, and sand conditions) or other incubation factors preclude development of the embryos, but it also varies the incubation environment of the eggs. In addition to sex ratio, the incubation environment has also been shown to influence among other things size, early swimming behavior, and early growth in hatchlings (Foley et al. 2006). Because the characteristics of hatchlings vary with incubation environments, a scattered nesting pattern also increases the variation of hatchling characteristics. This variation ensures that, at all times, at least some hatchlings have characteristics that are appropriate for survival. The exact characteristics that are best suited for survival vary unpredictably over space and time (Carthy et al. 2003). Relocating nests and/or concentrating them in one area of a beach (e.g., hatchery or corral areas) may very well reduce the variety of incubation environments that could influence the development of hatchling characteristics that increase survival rates (Foley et al. 2006).

In addition, handling eggs can result in increased hatch failure. When relocating nests, there is always a risk of disrupting the membranes inside the eggs, which can kill the embryos. Typically, a blanket policy of routinely relocating all or most turtle nests is seen as part of an intensive management effort to keep the species from going extinct, whereas allowing for natural breeding and nesting is the preferred option whenever available. The revised Loggerhead Sea Turtle Recovery Plan (NMFS and USFWS 2008) recommends the use of the least manipulative method to protect nests and states that as a general rule, nests should only be relocated if they are low enough on the beach to be washed daily by tide or if they are situated in well documented high-risk areas that routinely experience serious erosion and egg loss. Currently in North Carolina, the state permits sea turtle nest relocations for research or when there is an imminent threat and potential loss of the nest due to erosion or frequent flooding, but not to accommodate recreational uses. Nests in some states may be moved to avoid damage from beach nourishment or in highly developed urban areas (e.g., along some urban areas of Florida's Atlantic Coast). None of these special conditions apply at the Seashore. Consequently, routine relocation of all nests to allow for recreational access is not considered in this plan/EIS. However, the NPS would continue its current practice of coordinating with the State of North Carolina to consider relocating an individual nest facing inundation or other adverse factors.

**Turtles – Use Turtle Hatcheries.** Moving all nests or all relocated nests into one hatchery area is not fully analyzed as part of any alternative. Sea turtle nests may be moved to a guarded hatchery to provide needed protection from poaching in developing countries where participation in hatchery operations may be used as an eco-tourism opportunity. Some county or privately owned beaches in Florida or Georgia may use hatcheries for sea turtle eggs in some circumstances, such as to allow beach nourishment. However, county responsibilities for endangered or threatened species differ from federal, and particularly from NPS, responsibilities for these protected species. As a federal agency, the NPS has responsibilities under the ESA to protect the ecosystem as well as the species that depend on it. The purpose of the ESA is to “provide a means whereby the ecosystems upon which endangered species and threatened species depend may be conserved” (sec. 2(b)). Protecting the ecosystem is also necessary to meet the requirements of the *Organic Act*, which mandates the NPS to conserve Seashore wildlife (refer

to the “Other Applicable Federal Laws, Policies, Regulations and Plans” section in chapter 1 of this document).

Loggerhead sea turtles, the predominant nester at the Seashore, as well as leatherback and green sea turtles are all currently listed pursuant to the ESA. Any actions that would likely reduce productivity and cause a decline in the species would not be consistent with the purpose of the Act. The revised Loggerhead Sea Turtle Recovery Plan (NMFS and USFWS 2008) recommends the discontinuance of the use of hatcheries as a nest management technique and states that relocating nets into hatcheries concentrates eggs in an area and makes them more susceptible to catastrophic events and predation from both land and marine predators. It also can increase the potential for disease, such as fungal problems, to spread to all nests and result in egg mortality. Using corrals also usually results in hatchlings being released in the same location. This has the potential to increase predation in the ocean area surrounding the release site after the hatchlings reach the water. Therefore, use of hatcheries was not considered in this plan/EIS.

### **Modify the Turtle Program**

During public comment on the draft plan/EIS, commenters recommended modifying the turtle program to include nest relocation (discussed above), the use of volunteers (discussed below), different predator management techniques, varying buffer sizes, and varying the type of data collected for sea turtles. Under alternative F, sea turtle management procedures at the Seashore are based on the latest scientific research, and are consistent with the most current USFWS Recovery Plan for the Northwest Atlantic Population of the Loggerhead Sea Turtle (NMFS and USFWS 2008) and NCWRC guidelines (NCWRC 2006). Both documents have been developed by scientific experts in the field of loggerhead sea turtle biology and conservation. Additional information on why these elements were not carried forward can be found in “Appendix C: Concern Response Report” (see response to Concern ID 24193, 24143, and 24233).

### **Additions to the Shorebird Monitoring Program and Data Collection**

During public comment on the draft plan/EIS, commenters recommended additions to the Seashore’s bird monitoring and data gathering procedures including recording the GPS location for banded birds, that scopes be used rather than binoculars, use of experimental design comparing bird populations in areas open or closed to vehicles, and discontinuing use of the Southeast Coast Network (SECN) protocol for monitoring. A suggestion was also made that nonbreeding surveys be designed to occur at multiple distinct tidal stages. For the following reasons, NPS would continue to do what it has been doing for the nonbreeding shorebird surveys. First, SECN is the NPS Southeast Regional Office Inventory and Monitoring Program data collection arm, and it is appropriate for the Seashore to follow their technical guidance on monitoring methodology. Second, data collection techniques do not include larger transects because the counts are not meant to count every single bird, but are designed to show trends over time. Trends over time can be monitored without counting every bird. Third, the current transects are timed transects, which means they cannot be interrupted to obtain band data. Finally, the recently signed MOU between the USFWS and the NPS (<http://www.fws.gov/migratorybirds/Partnerships/NPSEO13186Signed%204.12.10.pdf>) commits NPS to working with its Inventory and Monitoring Program, of which SECN is a part, for migratory bird data collection.

### **Implement a Volunteer Program to Assist with Species Protection**

During public comment on the draft plan/EIS, some commenters recommended the Seashore use volunteers to implement a range of species management measures such as monitoring nesting activity, a beach watch program, and vehicle escorts. The primary purpose of the NPS volunteers in parks program is to use volunteer help that is mutually beneficial to the NPS and the volunteer. The NPS recognizes the importance of encouraging stewardship through volunteer opportunities and will use volunteers when deemed appropriate and resources are available to run such a program. The NPS will work at integrating volunteers back into the less sensitive aspects of the species monitoring program. At this time, NPS believes that the best use of volunteers for species protection activities would be in a trained volunteer program for watching sea turtle nests that have reached their hatch windows to monitor hatchling emergence and success reaching the water, and to inform the public on ways to minimize negative impacts from artificial lighting, predation, and human disturbance. This program should enhance protection and encourage ownership/stewardship of resources among the public, and provide a beneficial situation for both the NPS and the volunteers. However, at this time, with the current controversy over ORV and protected species management, using volunteers to act as vehicle escorts or to monitor nesting activity (such as the morning sea turtle patrol) is not feasible as an alternative element because actions taken by trained park staff are so closely scrutinized and criticized and the NPS would not want to ask volunteers to be responsible for implementing controversial on-site activities or decisions.

### **Create an Oversight Committee with External Experts and Scientists**

Creating an oversight committee with external experts and scientists under the *Federal Advisory Committee Act* (FACA) has been considered but dismissed as a reasonable alternative for further analysis. FACA restricts the establishment of such committees to situations “when they are determined to be essential” (FACA sec 2(b)(2)). The creation of the suggested oversight committee is not “essential.” In its practical application, a FACA committee would be mostly redundant with the current NPS process of seeking scientific and technical consultation or advice as required or appropriate from species scientific experts in other agencies, organizations, and academia. Additionally, the significant administrative costs in staff time and money incurred in establishing and maintaining a FACA committee are not warranted when the needed scientific advice can be obtained less expensively and more efficiently. Based on the recent NPS experience with the negotiated rulemaking committee, established under FACA, the suggested oversight committee would not be likely to provide the NPS with clear and consistent, actionable advice, and managing the committee would require a commitment of staff time that could not be sustained over the life of the plan.

### **Open All Closed Areas after Breeding Season Is Over**

Commenters suggested that all closed areas should be reopened after the breeding season ends. Most closed areas would likely be reopened after the breeding season if the areas do not provide important migrating and wintering habitat for Seashore populations of protected species. Therefore, some areas may be reopened, but automatically opening all closed areas after the breeding season would be inconsistent with the Seashore’s responsibility under various statutes, including its enabling legislation, the *Organic Act*, the ESA, the MBTA, and the *NPS Management Policies 2006*, section 4.4.2.3. The alternatives in the plan/EIS do consider various ways to address resource-based closures, but the alternatives do not allow for automatic opening after the breeding season is over if species are still present.

### **Create New Habitat**

Commenters suggested various ways that habitat could be created to provide alternative areas for bird species at the Seashore. Some of these suggestions included letting ORVs drive on the vegetation to

create habitat or physically creating habitat using dredge material in the sound or by other means. These suggestions were considered by the Seashore but are not carried forward in this plan/EIS for the following reasons:

- **Allow visitors in ORVs to enhance habitat by driving over vegetated areas.** It has long been documented that even a low level of ORV use can cause severe degradation of coastal vegetation (Leatherman and Godfrey 1979). The Seashore recognizes that ORV use at certain locations could be an effective way to manage the encroachment of vegetation into existing shorebird nesting habitat. However, use of ORVs to create new habitat implies a large-scale use of vehicles to remove vegetation, which is typically protected under various NPS regulations and under the Executive Orders on ORV use. While removal of vegetation by any means to create new habitat may be appropriate and beneficial in certain circumstances, such a project would need to be planned, implemented, and studied by scientists or resource managers with the appropriate expertise. Therefore, allowing visitors in ORVs to create habitat was not considered in this plan/EIS.
- **Create habitat through physical alteration or the creation of dredge islands.** The NPS considered creating habitat through various methods. Based on the experience of staff at the NCWRC, habitat-creation projects tend to be short-lived and labor intensive. Based on experience with hand pulling, herbicides, fires, and bulldozing, it was found that most of these techniques are effective for only one season before the vegetation returns. Covering areas with new dredge material has been shown to last longer, with vegetation returning after four to seven years (Cameron pers. comm. 2007). Although the NPS recognizes that creation of habitat may be viable under certain circumstances, it is not an appropriate substitute for providing adequate protection of existing habitat. If this method is employed, it would occur outside the scope of the plan/EIS and therefore was not included in the alternatives.

### **Fence Chicks Away from the ORV Corridor**

Commenters suggested using barrier fencing, rather than symbolic fencing, to keep chicks away from the ORV corridors. Unfledged piping plover and American oystercatcher chicks need access to the intertidal zone and moist substrate habitat for foraging and chicks of all beach nesting bird species may utilize those same areas for thermal regulation. Fencing chicks away from these areas would essentially reduce their chances of survival; therefore, this was not considered a reasonable alternative.

### **Do Not Provide Protection to the Seabeach Amaranth**

Commenters suggested that seabeach amaranth is a “farmed” plant and should not be offered special protection. However, the seabeach amaranth is protected as a federally listed threatened plant species. Under the ESA, federal agencies are required to use their authority in furtherance of the purposes of the ESA by carrying out programs for the conservation of endangered and threatened species and to ensure that any agency action authorized, funded, or carried out by the agency is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of designated critical habitat. Further, NPS *Management Policies 2006* state that “the Service will survey for, protect, and strive to recover all species native to national park system units that are listed under the *Endangered Species Act*” (NPS 2006c). The management policies also state that the NPS will “successfully maintain native plants and animals by preserving and restoring the natural abundances, diversities, dynamics, distributions, habitats, and behaviors of native plant and animal populations and the communities and ecosystems in which they occur; restoring native plant and animal populations in parks when they have been extirpated by past human-caused actions; and minimizing human impacts on native plants, animals, populations, communities, and ecosystems, and the processes

that sustain them.” Not providing protection to a federally listed threatened species would be out of compliance with the ESA and contrary to the NPS *Management Policies 2006*, and was therefore not included in the alternatives of this plan/EIS.

### **Give Special Consideration only to Flora and Fauna Listed as Threatened or Endangered**

Commenters suggested that only those species listed as threatened or endangered under the federal ESA should be considered in this plan/EIS. As stated above, the NPS has legal responsibilities under the ESA and its own policies to protect threatened and endangered species. Further, a number of laws, regulations, and policies, in addition to the ESA, guide species management at the Seashore, including the *Organic Act*, the MBTA, NPS regulations and policies, Executive Orders 11644 and 11989: Use of Off-Road Vehicles on the Public Lands (see chapter 1), Executive Order 13186: Responsibilities of Federal Agencies to Protect Migratory Birds, and others (see chapter 1). Executive Order 11644 provides that areas designated for ORV use shall be located to minimize harassment of wildlife or significant disruption of wildlife habitats. NPS *Management Policies 2006* section 4.4.2.3 states, in part, that the NPS will inventory, monitor, and manage state- and locally listed species in a manner similar to its treatment of federally listed species to the greatest extent possible. In addition, the NPS will inventory other native species that are of special management concern to parks (such as rare, declining, sensitive, or unique species and their habitats) and will manage them to maintain their natural distribution and abundance. The combination of laws, regulations, and policies included in this section of the plan/EIS create the framework in which the alternatives are developed, which includes the need to manage species that are considered to be of special concern, such as state-listed species, or those addressed by the MBTA. Because of these responsibilities, only considering flora and fauna listed as federally threatened or endangered was not included in the plan/EIS alternatives.

## **OTHER ISSUES**

### **Rebuild the Dunes**

One commenter suggested the NPS rebuild the dunes in front of NC-12. While the NPS had engaged in dune rebuilding activities in the past, such as to protect NPS structures on Bodie Island, this activity is beyond the scope of this plan/EIS and could be addressed later in the general management plan process that the Seashore will undertake in the future.

### **Prohibit Gill Net Fishing**

Some commenters asked that the Seashore prohibit gill net fishing. Fishing activities, both commercial and recreational, require a Standard Commercial Fishing License or a Recreational Commercial Gear License from the state of North Carolina. The license and related state fishing regulations specify the type of nets that commercial fishermen are allowed to use, which includes the use of gill nets that conform to requirements for mesh size, yardage, and marking (NCDMF 2009). The type of gear used by commercial fisherman is outside the scope of this plan; therefore, it was not included as an element of the plan/EIS.

### **Provide an Area for Off-Leash Dogs**

Commenters suggested that dogs be allowed off leash at the Seashore, either seasonally, in certain areas of the Seashore under voice control, or through the creation of a dog-training area. Currently, pets at the Seashore are regulated under 36 CFR 2.15, which applies to all units of the national park system and prohibits pet owners from “failing to crate, cage, restrain on a leash which shall not exceed 6 feet in length, or otherwise physically confine a pet at all times.” Creation of off-leash areas would not be

consistent with 36 CFR 2.135 and would require its own planning process and promulgation of a special regulation allowing off-leash dog use, which is outside the scope of the plan/EIS.

## **CONSISTENCY WITH THE PURPOSES OF NEPA**

The NPS requirements for implementing NEPA include an analysis of how each alternative meets or achieves the purposes of NEPA, as stated in sections 101(b) and 102(1). Each alternative analyzed in an EIS must be assessed as to how it meets the following purposes:

1. Fulfill the responsibilities of each generation as trustee of the environment for succeeding generations.
2. Ensure for all Americans safe, healthful, productive, and esthetically and culturally pleasing surroundings.
3. Attain the widest range of beneficial uses of the environment without degradation, risk of health or safety, or other undesirable and unintended consequences.
4. Preserve important historic, cultural, and natural aspects of our national heritage and maintain, wherever possible, an environment that supports diversity and variety of individual choice.
5. Achieve a balance between population and resource use that will permit high standards of living and a wide sharing of life's amenities.
6. Enhance the quality of renewable resources and approach the maximum attainable recycling of depletable resources.

CEQ Regulation 1500.2 establishes policy for federal agencies' implementation of NEPA. Federal agencies shall, to the fullest extent possible, interpret and administer the policies, regulations, and public laws of the United States in accordance with the policies set forth in NEPA (sections 101(b) and 102(1)); therefore, other acts and NPS policies are referenced as applicable in the following discussion.

1. Fulfill the responsibilities of each generation as trustee of the environment for succeeding generations.

As noted in the analysis, alternatives B, C, D, E, and F provide increased protection for sensitive species at the Seashore, through increased resource protection buffers and limitations on recreational access. Limitations on access would not only benefit threatened, endangered, and special status species, but would also provide protection to other physical resources at the Seashore such as wetlands, vegetation, and other wildlife.

Alternative D would provide year-round SMAs that would limit recreational access in these areas, particularly during the breeding season, and would offer the greatest level of species protection among the action alternatives. Through these access limitations, as well as other provisions such as seasonal night-driving restrictions and the implementation of a permit system that would provide user education and increase awareness alternative D would fully meet the purpose of fulfilling the responsibilities of each generation as trustee of the environment for succeeding generations, by providing the greatest potential for the survival of sensitive species in the long term, while at the same time protecting other physical resources of the Seashore. Alternatives C, E, and F would meet this purpose to a large degree but not fully because of greater potential for impacts to sensitive species from human disturbance as shorebird breeding habitat in some locations would include pedestrian or ORV access corridors, thereby increasing recreational

access to these sensitive areas. Alternatives E and F would not offer the same level of seasonal night-driving restrictions, with less hours closed each night, providing a somewhat lesser level of protection than alternatives C and D. Further, providing opportunities for access either through park-and-stay or SCV camping under alternative E would also increase recreational access, introducing potential disturbance to protected species, as well as other physical resources at the Seashore.

Alternative B would only meet this purpose to a moderate degree, as seasonal night-driving restrictions would offer the species additional protection, but without the SMAs, the proactive restriction of recreation would not be in place and could result in long-term threats to sensitive species from recreational use. Alternative A would only meet this purpose to some degree as there would be no seasonal night-driving restrictions and buffers would require frequent adjustments to provide adequate protection, thereby not providing optimal protection for the species.

2. Ensure for all Americans safe, healthful, productive, and esthetically and culturally pleasing surroundings.

All alternatives meet this purpose to some degree because the Seashore is a safe visitor destination that is both esthetically and culturally pleasing. The action alternatives (alternatives C, D, E, and F) increase safety by establishing a 15 mph speed limit within the entire Seashore. For pedestrian user groups, the establishment of vehicle-free areas, particularly under alternative D, may provide the greatest safety and esthetic benefits as pedestrian and vehicular uses would be separated. However, alternative D does not establish any safety closures although most areas historically closed for safety reasons would be closed under alternative D. Alternative F would provide additional safety benefits by establishing right-of-way requirements and additional speed limit reductions when pedestrians are present. Also under the action alternatives, the designation of ORV routes and vehicle-free areas would reduce the potential for, as well as the perception of, visitor conflict issues. Although actual visitor conflicts may not always happen when these two uses occur in the same area, providing vehicle-free areas would eliminate the potential for conflicts in those areas and address the feeling of those who perceive there could be a conflict or other safety issue. Of all the alternatives, alternative A would meet this purpose to the least degree, as it would not separate vehicular and pedestrian uses to the degree that the action alternatives would, and off-season speed limits would remain at 25 mph. Likewise, alternative B lowers speed limits, but still does not provide separation of uses and would not address any perceived safety or conflict issues associated with having ORV and non-ORV use in the same area. Although alternatives C, D, and E would meet this purpose to a large degree, alternative F would fully meet this purpose by establishing a reduced speed limit, providing some level of pedestrian and vehicular separation, and establishing right of way requirements not present in the other alternatives.

3. Attain the widest range of beneficial uses of the environment without degradation, risk of health or safety, or other undesirable and unintended consequences.

All alternatives offer a wide range of visitor use opportunities, including vehicular use, recreational fishing, swimming, walking, sunbathing, other general beach recreation, and commercial fishing. However, the intensity of recreational use allowed under a particular alternative could lead to resource degradation or risks to health and safety. Alternative A allows the most intense levels of ORV and pedestrian use that could potentially lead to environmental degradation and safety concerns and only meets this purpose to some degree. Alternative B provides additional protection of natural resources through the establishment of larger buffers and

restrictions on night driving for sea turtle protection. However, this alternative does not directly address the level of recreational use and any safety or environmental concerns that may be associated with increasing visitor use patterns. Under alternative B, which bases closures on species behavior, there is the potential for large areas of the Seashore to be closed and these areas would vary from season to season based on protected species breeding behavior. Therefore, alternative B meets this purpose to a moderate degree due to added protection for sensitive species, but does not meet it to a larger degree because the provision of other uses of the Seashore would be unpredictable. Action alternatives C, D, and E include the establishment of SMAs, while alternative F relies on prenesting closures and standard buffers when breeding activity is observed, to reduce the disturbance of sensitive species habitat. These measures, combined with increased resource protection buffers, reduced speed limits, some measure of separation of vehicular and pedestrian uses, and methods for establishing a carrying capacity to reduce the environmental and safety concerns associated with large numbers of vehicles and pedestrians in one area. Therefore, all action alternatives would meet the intent of this purpose to a moderate or large degree. However, alternative D would reduce the potential for environmental impacts and visitor conflicts by prohibiting vehicles in all SMAs year-round. Therefore, alternative D would fully meet this purpose.

4. Preserve important historic, cultural, and natural aspects of our national heritage and maintain, wherever possible, an environment that supports diversity and variety of individual choice.

Because none of the alternatives would result in impacts to cultural or historic resources that would exceed minor, these topics were dismissed from further analysis in this plan/EIS. Overall, since any impacts to cultural or historic resources would not exceed minor, all alternatives would preserve important historic and cultural aspects of our national heritage in the long term and would meet this purpose to a large degree, with alternatives that restrict recreational access seasonally and at night (alternatives B, C, D, E, and F), meeting it for natural resources to a larger degree than alternative A. As discussed under criteria 1 and 2, due to use restrictions, alternatives C, D, E, and F would better protect resources, which would in turn support diversity, and due to the separation of visitor uses and addition of visitor amenities, would better support a variety of individual choices than alternatives A and B.

5. Achieve a balance between population and resource use that will permit high standards of living and a wide sharing of life's amenities.

Balancing population and resource use under the plan/EIS would include protecting the resources unimpaired for the enjoyment of present and future generations and providing access for visitors to experience the natural resources of the Seashore. NPS *Management Policies 2006* states that the enjoyment that is contemplated by the *Organic Act* is broad; it is the enjoyment of all the people of the United States and includes enjoyment both by people who visit parks and by those who appreciate them from afar. It also includes deriving benefit (including scientific knowledge) and inspiration from parks, as well as other forms of enjoyment and inspiration. Congress, recognizing that the enjoyment by future generations of the national parks can be ensured only if the superb quality of park resources and values is left unimpaired, has provided that when there is a conflict between conserving resources and values and providing for enjoyment of them, conservation is to be predominant. As discussed above, alternatives C, D, E, and F would provide species management strategies that include prenesting areas, standardized buffers when breeding activities are observed, and seasonal night-driving restrictions, as well as implementation of a permit system, all of which are expected to benefit the natural resources at the Seashore and would provide an amenity (resources) for visitors to experience that would permit a high standard of living. All of the alternatives evaluated would allow some level of access to the Seashore that

would contribute to the sharing of these amenities. As visitation to the Seashore increases and the population of the area continues to increase, having areas with designated resource closures under the action alternatives would contribute to the protection of the Seashore's natural resources.

Given this, alternatives A and B would meet this purpose to some degree because they would provide the public access to share these amenities, but would not offer a high level of protection to natural resources. Without a higher level of protection, these amenities may not be available for the enjoyment of future generations.

Alternatives C and E would provide access to the Seashore and the amenities therein, and offer protection of these amenities by establishing SMAs and by implementing seasonal night-driving restrictions. In alternatives C and E, some of the SMAs would be under ML2 management measures, which would provide a higher level of access and use to those areas (including ORV and pedestrian corridors). Alternative F would provide access to the Seashore and the amenities therein, and would protect sensitive wildlife habitat through the designation of year-round ORV routes and vehicle-free areas, the use of prenesting closures in some locations, and standard buffers (similar to ML2) in all locations, and by implementing seasonal night-driving restrictions. Under alternatives C, E, or F, allowing this level of use, particularly as the population grows, may not fully protect the natural resources at the Seashore. As access to certain areas of the Seashore may adversely impact some of the Seashore's natural resources, especially in light of population growth, alternatives C, E, and F would only meet this purpose to a moderate degree.

Alternative D would meet this purpose to a large degree by establishing SMAs that are closed to ORV use and pets year-round, and pedestrians during the breeding season. Establishing these areas, year after year, would ensure a level of protection that would allow the natural resources to remain amenities that contribute to a high standard of living, while providing a level of access to the Seashore beaches that would ensure that the visiting public would be able to share these amenities.

6. Enhance the quality of renewable resources and approach the maximum attainable recycling of depletable resources.

For reasons discussed above, in varying degrees the action alternatives (alternatives C, D, E, and F) would enhance the quality of the Seashore's biological and physical resources. Alternative B also provides a greater level of protection for these resources than alternative A. The second purpose, "approach the maximum attainable recycling of depletable resources," is less relevant to an ORV management plan, as it is geared toward a discussion of "green" building or management practices. There would be no construction related to the no-action alternatives, so this purpose would not apply. The action alternatives would involve the construction of new ramps and parking areas using environmentally appropriate design standards to minimize stormwater runoff. Ramps would be constructed of a semi-permeable natural clay/shell base.

However, as discussed in chapter 1 of this document, each of the alternatives would require that the Seashore continue to operate under the wise energy use guidelines and requirements stated in the *NPS Management Policies 2006*; Executive Order 13123, *Greening the Government Through Effective Energy Management*; Executive Order 13031, *Federal Alternative Fueled Vehicle Leadership*; Executive Order 13149, *Greening the Government Through Federal Fleet and Transportation Efficiency*; and the 1993 NPS *Guiding Principles of Sustainable Design* and therefore would fully meet this purpose.

## ENVIRONMENTALLY PREFERABLE ALTERNATIVE

The NPS is required to identify the environmentally preferable alternative in its NEPA documents for public review and comment. The NPS, in accordance with the U.S. Department of the Interior policies contained in the Department Manual (515 DM 4.10) and CEQ's Forty Questions, defines the environmentally preferable alternative (or alternatives) as the alternative that best promotes the national environmental policy expressed in NEPA (section 101(b)) (516 DM 4.10). The CEQ's Forty Questions (Q6a) further clarifies the identification of the environmentally preferable alternative stating, "this means the alternative that causes the least damage to the biological and physical environment; it also means the alternative which best protects, preserves, and enhances historic, cultural, and natural resources."

Alternative D was identified as the environmentally preferable alternative because it best protects the biological and physical environment by

- Providing SMAs in known breeding/nesting areas throughout the Seashore, all under ML1 management. Specifically, these SMAs would provide the following:
  - A proactive way to protect large areas of the Seashore where protected species are known to breed and nest by prohibiting ORV use and pets in these areas year-round and only allowing pedestrian access outside of the breeding season.
  - The greatest level of spatial and temporal protection through the establishment of SMAs that are all managed under ML1 procedures year-round.
  - A benefit to wintering bird populations at the Seashore that would also utilize the large vehicle-free areas provided under the SMAs for alternative D.
  - Buffers around those species found breeding/nesting outside the SMAs, further offering protection to protected species and species of concern at the Seashore.
  - Large, year-round ORV-free areas that would benefit other protected species, including sea turtles and seabeach amaranth.
  - A level of predictability to ORV users at the Seashore that would be expected to decrease the level of non-compliance with species management measures.
- Including seasonal night-driving restrictions in areas where ORVs are permitted that would restrict nighttime use from 7:00 p.m. to 7:00 a.m. from May 1 to November 15. The seasonal duration of the closures, as well as the length of the nightly closure, would offer protection to sea turtles nesting and hatching during that time, and allow Seashore staff the time to record and document nests each morning, decreasing the possibility of undiscovered nests.
- Minimizing the extent and location of interdunal roads, ramps, or parking lots that would be added, further minimizing disturbance under this alternative, when compared to alternatives C, E, and F.
- Implementing a permit system to provide ORV users with education that is expected to decrease the level of non-compliance related to resource closure areas.

Overall, establishing SMAs that are closed year-round to ORVs and pets, and closed to pedestrians during the breeding season, along with seasonal night-driving restrictions beginning at 7:00 p.m., the least amount of construction of all the alternatives, and required buffers for all protected species found outside the SMAs, would best protect, preserve, and enhance the Seashore's resources.

## NATIONAL PARK SERVICE PREFERRED ALTERNATIVE

To identify the preferred alternative, the planning team evaluated each alternative based on its ability to meet the plan objectives (see table 12) and the potential impacts on the environment (see chapter 4 of this document). Alternative F was identified as the NPS preferred alternative. Based on public and agency comments received on the draft plan/EIS, the NPS has revised the preferred alternative as described in this document (the final plan/EIS).

Both alternatives D and F would meet most of the plan objectives either fully or to a large degree. In terms of species protection, both alternatives would provide the necessary buffers, as well as the proactive establishment of prenesting areas and protection of breeding and nonbreeding shorebird habitat. Seasonal night-driving restrictions would be similar under both of these alternatives, offering comparable protection to sea turtles and foraging bird species. However, alternative F was chosen as the preferred alternative because it would provide not only effective resource protection but also would provide Seashore visitors with more diverse options for access and recreational use. Providing approximately 26 miles of the Seashore that are designated vehicle-free areas year-round, while 28 miles are open to ORV use year-round (subject to resources closures), would provide for a greater diversity of visitor use. Although designation of all SMAs as year-round ORV closures under alternative D would provide the necessary resource protection, the use of ML1 buffers in all SMAs would preclude all visitor access in these areas during the breeding season. If protected species do not use portions of the SMAs or if conditions of the Seashore change and habitat changes, alternative D does not provide as much flexibility for the Seashore to manage visitor access as alternative F, which provides for designated ORV routes that would remain open unless protected species activity results in a resource closure. In addition to providing species protection both during the breeding and nonbreeding seasons, alternative F would also provide more flexibility and range of experience for visitor use and would enhance access to both vehicle-free areas and designated ORV routes by establishing strategically located new parking areas, pedestrian trails, interdunal routes, and ORV ramps. Because alternative F provides for a greater variety of uses throughout the Seashore, it would have less of an impact on the socioeconomics of the area as well. As detailed in the impact analysis in chapter 4, alternative D would have greater impacts to the economy of the villages within the Seashore. In addition, alternative F also would mitigate the potential economic and visitor impacts by encouraging alternative forms of access (water taxi and beach shuttle) to certain popular areas during times when they may be open for pedestrian use, but the access to the area may be closed due to a resource closure. By providing an alternate means for accessing these areas, beneficial economic impacts would be expected. Alternative F is also selected as the NPS preferred alternative because it incorporates some concepts and measures that originated in or were discussed during the negotiated rulemaking process, providing more public input. For these reasons, alternative F was selected as the preferred alternative.

Alternatives C and E would meet the objectives from a moderate to a large degree, but to a lesser degree when compared to alternative D because of the larger areas of recreational access allowed. By allowing more access to various areas of the Seashore during the breeding season of threatened, endangered, and species of special concern, the level of protection offered to these species would be less than alternative D.

Alternatives A and B, on the whole, would meet the objectives from some degree to a moderate degree. These alternatives would not meet key objectives (such as those related to providing protection for threatened and endangered species and minimizing impacts to other natural resources at the Seashore) as well as the action alternatives. Because these alternatives would not meet the objectives to a large degree, they were not selected as the preferred alternative.

Intentionally Left Blank

TABLE 7. OFF-ROAD VEHICLE ROUTES AND AREAS – ALTERNATIVES A, B, C, D, AND E

Oceanside Location	Mileage <sup>a</sup>	Alternatives A and B: No Action	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management
<b>Bodie Island (north to south)</b> Ramp 1 to north end of Coquina Beach	0.9	OPEN <sup>b</sup> Seasonally closed May 15 to Sep 15 (longstanding safety closure).	ORV route—Mar 15 to Oct 14 VFA—Oct 15 to Mar 14	X	X Parking at ramp 1 expanded.
North end of Coquina Beach to 0.5 mile south of Coquina	0.8	OPEN <sup>b</sup> Seasonally closed May 15 to Sep 15 (longstanding safety closure). South of ramp 2 at Coquina Beach open seasonally.	X Ramp 2 relocated approx. 0.5 mile south of Coquina Beach.	X Ramp 2 relocated approx. 0.5 mile south of Coquina Beach.	X Ramp 2 relocated approx. 0.5 mile south of Coquina Beach. When shorebird breeding activity is observed, standard buffers would apply, which depending upon the circumstances could close the access corridor. NPS would also allow water taxi service to spit from Silver Lake, subject to designated landing zone and resource closures. (ML2)
Inlet shoreline along South Point	1.0	OPEN YR <sup>b</sup>	X	X	X

Oceanside Location	Mileage <sup>a</sup>	Alternatives A and B: No Action	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management
--------------------	----------------------	---------------------------------	------------------------------------	---	---

NOTES: Details on soundside access provided in table 8. Due to updated base mapping, the shape of the inlets and spits was updated for alternative F maps, resulting in a slight difference in mileage between alternative F and the other alternatives (see table 7-1).

<sup>a</sup> All mileages are approximate.

<sup>b</sup> Area(s) open to ORV use, except when resource, seasonal, or safety closures are in effect.

Designated ORV routes and areas (ORV route = ORV permitted, X = VFA (vehicle-free area); YR = year-round).

All ORV routes and areas subject to temporary resource closures.

**Species Management Areas (SMAs):** ML1 and ML2 are the two proposed strategies for species management. See table 10 for a detailed description of these strategies. All areas outside of designated SMAs would be managed under ML1 protocols.

(ML1) Once prenesting closures are established, ORV and pedestrian access would be prohibited until breeding activity is completed.

(ML2) Once prenesting closures are established, ORV or pedestrian access corridor(s) and/or boat landing areas (as indicated in the respective alternatives) would be permitted. Upon the first observation of breeding activity, standard ML2 buffers would apply, which depending upon the circumstances may close the access corridor.

Designated ORV Route Mileage (Approximate) <sup>f</sup>	Alternative A <sup>c</sup>	Alternative B <sup>c</sup>	Alternative C	Alternative D	Alternative E
Designated as ORV route YR	49.4	50.1	27.4	27.2	31.6
Designated for seasonal ORV use	17.9	16.2	27.0	0	20.2
Designated as Vehicle Free Area YR (X) <sup>e</sup>	0 <sup>d</sup>	1.0	12.9	40.1	15.5
Total	67.3	67.3	67.3	67.3	67.3

<sup>c</sup> Routes under alternatives A and B have not been officially designated for ORV use. The mileages shown in this table are based on areas open to ORV use under the Interim Protected Species Management Strategy and the consent decree.

<sup>d</sup> Does not include mileage closed for safety reasons.

<sup>e</sup> Miles designated as closed to ORV year-round do not include the 12 miles at Pea Island National Wildlife Refuge where vehicles are not permitted. Including the mileage of Pea Island, areas designated closed to ORVs year-round would be as follows: Alternative C = 24.9; Alternative D = 52.1; Alternative E = 27.5

TABLE 7-1. OFF-ROAD VEHICLE ROUTES AND AREAS – ALTERNATIVE F

Oceanside Location	Mileage	Alternative F: Preferred Alternative
<b>Bodie Island (north to south)</b> Ramp 1 to 0.5 miles south of Coquina Beach	1.7	X Parking at old Bodie Island Coast Guard Station site (use existing asphalt-paved parking area, or resurface using pervious material after site is used as a potential staging area for proposed widening and repaving of NC12)

Ramp 68 to 0.4 miles northeast of ramp 70 (includes Ocracoke Day Use area)	2.2	X
0.4 mile northeast of ramp 70 to Ocracoke Inlet (includes ramp 72)	4.1	ORV route YR
Inlet shoreline along South Point	1.0	X

NOTES: Details on soundside access provided in table 8. Parking areas indicated above would be accessible to 2-wheel drive vehicles.

All mileages are approximate.

Designated ORV routes and areas (ORV route = ORV use permitted; X = VFA (vehicle-free area); YR = year-round).

ORV routes are subject to safety closures and temporary resource closures. VFAs are subject to temporary resource closures.

Designated ORV Route Mileage (Approximate <sup>a</sup> )	Alternative F
Designated as ORV Route YR	27.9
Designated for seasonal ORV use	12.7
Designated as vehicle-free area YR (X) <sup>b</sup>	26.4
Total	67 <sup>c</sup>

<sup>a</sup> All mileages are approximate

<sup>b</sup> Miles designated as vehicle-free area year-round does not include the 12-miles at Pea Island National Wildlife Refuge where vehicles are not permitted. Including the mileage of Pea Island, areas designated closed to ORVs year-round would equal 38.4 miles under alternative F.

<sup>c</sup> Due to updated base mapping, the shapes of the inlets and spits were updated for maps of alternative F, resulting in a slight difference in mileage between alternative F and the other alternatives.

**TABLE 8. SUMMARY OF ALTERNATIVE ELEMENTS**

This matrix is designed to display differences among alternatives; therefore, actions common to all alternatives are not included in it. Refer to the “Elements Common to All Alternatives” section, which begins on page 56 of chapter 2.

Alternative A: No Action— Continuation of Management under the Interim Strategy	Alternative B: No Action— Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>ORV Routes, Use Areas, and Corridors</b>					
<p><b>ORV use areas:</b> All areas of the Seashore are potentially open to ORV access, except when closed as described in Superintendent’s Order 7. Visitors accessing the Seashore by ORV must drive only on marked ORV routes and must comply with posted restrictions. Refer to table 7.</p> <p><b>ORV corridors:</b> The ORV corridor on the ocean beach is marked by posts placed approx. 150 feet landward from the average, normal high tide line, or if less than 150 feet of space is available, at the vegetation or the toe of the remnant dune line, except as noted in the Interim Strategy. The corridor width will fluctuate over time due to the dynamic nature of beach and surf.</p>	<p><b>ORV use areas:</b> Same as alternative A.</p> <p><b>ORV corridors:</b> Same as alternative A, except: Mar 15 to Nov 30: In all locations not in front of the villages that are open to ORV use, NPS shall provide an ORV-free zone in the ocean backshore at least 10 meters wide, wherever there is sufficient beach width to allow an ORV corridor of at least 20 meters above the mean high tide line.</p>	<p><b>ORV routes:</b> ORV access would be prohibited in all areas of the Seashore except where an ORV route is specifically designated. An <i>ORV route</i> is a designated location, typically linear in nature (e.g., from point A to point B), where ORV travel may be authorized by the Superintendent, but which may be temporarily closed to ORV use to protect Seashore resources, provide for visitor safety, or prevent user conflicts. Refer to table 7.</p> <p><b>ORV corridors:</b> An <i>ORV corridor</i> is the actual physical demarcation of the ORV route in the field. The ORV corridor on the ocean beach would be marked by posts seaward of the toe of dune or vegetation line to the high tide line (the seaward side of the corridor would not be posted). ORV routes through vegetated areas, such as interdunal roads and ramps, would be posted on both sides of the corridor.</p> <p><b>Seasonally designated ORV routes:</b> These would occur as indicated in table 7.</p>	<p><b>ORV routes:</b> ORV access would be prohibited in all areas of the Seashore except where an ORV route is specifically designated. The definition of ORV route is same as for alternative C.</p> <p><b>ORV corridors:</b> Same as alternative C.</p> <p><b>Seasonally designated ORV routes:</b> No seasonal designations under this alternative.</p>	<p><b>ORV routes:</b> ORV access would be prohibited in all areas of the Seashore except where an ORV route is specifically designated. The definition of ORV route is same as for alternative C.</p> <p><b>ORV corridors:</b> Same as alternative C, except: Mar 15 to Aug 31: Where the ocean beach is at least 30 meters wide above the high tide line, the corridor would be posted 10 meters seaward of the toe of the dune to provide an ocean backshore closure.</p> <p><b>Seasonally designated ORV routes:</b> These would occur as indicated in table 7.</p>	<p><b>ORV routes:</b> ORV access would be prohibited in all areas of the Seashore except where an ORV route is specifically designated. The definition of ORV route is same as for alternative C.</p> <p><b>ORV corridors:</b> Same as alternative C, except: Year-round: Where the ocean beach is at least 30 meters wide above the high tide line, the corridor would be posted 10 meters seaward of the toe of the dune to provide an ocean backshore closure.</p> <p><b>Seasonally designated ORV routes:</b> These would occur as indicated in table 7-1.</p>

<b>Pedestrian Safety</b>					
<p>36 CFR 4.20, Right-of-Way: An operator of a motor vehicle shall yield the right of way to pedestrians (as well as saddle and pack animals, and vehicles drawn by animals). Failure to yield the right of way is prohibited.</p> <p>36 CFR 4.22, Unsafe Operation: (b) The following are prohibited:</p> <p>(3) Failing to maintain that degree of control of a motor vehicle necessary to avoid danger to persons, property, or wildlife.</p> <p>No additional measures apply.</p>	Same as alternative A.	Same as alternative A.	Same as alternative A.	Same as alternative A, plus: <ul style="list-style-type: none"> <li>For village beaches that are open to ORV use during the winter season, the village beaches must be at least 20 meters (66 feet) wide from the toe of the dune seaward to mean high tide line in order to be open to ORV use.</li> </ul>	Same as alternative A, plus: <ul style="list-style-type: none"> <li>Vehicles must yield to pedestrians on all ORV routes.</li> <li>When approaching or passing a pedestrian on the beach, ORVs shall move to the landward side of the available ORV corridor in order to yield the wider portion of the beach corridor to the pedestrian.</li> <li>ORVs shall slow to 5 mph when traveling within 30.5 meters (100 feet) or less of pedestrians at any location on the beach at any time of year.</li> <li>Pedestrians should not block access ramps and should use pedestrian ramps/boardwalks where available. If a pedestrian walkover is not available, pedestrians should walk to the side of ORV ramps, not in the tire tracks.</li> </ul>
<b>Administrative ORV Closures</b>					
The beach in front of the former site of Cape Hatteras Lighthouse is closed to ORV access.  Buxton Woods Road is closed to ORV access.	Same as alternative A.	No administrative closures would be established. ORV routes and VFAs would be designated as described in table 7.	Same as alternative C.	Same as alternative C.	Same as alternative C.
<b>Temporary Emergency ORV Closures</b>					
Temporary emergency ORV closures established per Superintendent's Compendium and NPS policy.	Same as alternative A, plus: <ul style="list-style-type: none"> <li>NPS retains the authority to implement a temporary emergency ORV closure if any of the following conditions are observed:</li> <li>ORV traffic is backing up on the beach access ramps, either on- or off-beach bound, which threatens to impede traffic flow.</li> <li>ORV traffic on the beach is parked in such a way that two-way traffic is impeded.</li> </ul> Multiple incidents of disorderly behavior are observed or reported.	Same as alternative B, plus: <ul style="list-style-type: none"> <li>Beaches would be temporarily closed to additional ORV use if/when carrying capacity is reached or exceeded.</li> </ul>	Same as alternative B.	Same as alternative C.	Same as alternative B, plus: <ul style="list-style-type: none"> <li>Beaches would be temporarily closed to additional ORV use if/when carrying capacity or one-vehicle-deep beach parking limit is reached or exceeded.</li> </ul>

Alternative A: No Action— Continuation of Management under the Interim Strategy	Alternative B: No Action— Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Ramp Characteristics</b>					
Ramp width and construction details vary. Current practice is to use shell/clay base material to provide firm driving surface where ramps cross dune line.	Same as alternative A.	Ramps would be two lanes wide with shell/clay base and have: <ul style="list-style-type: none"> <li>• Standard regulatory signs and information boards at all ramps.</li> <li>• Gates at all ramps and access points.</li> <li>• Designated “air down” area with hardened surface (e.g., shell/clay base).</li> </ul>	Same as alternative C.	Same as alternative C.	Same as alternative C.
<b>Permit Requirements</b>					
No permit required.	Night-driving permit required for ORV use from 10:00 p.m. to 6:00 a.m. Sep 16 to Nov 15.	ORV permit required.	Same as alternative C.	Same as alternative C.	Same as alternative C.
<b>Permit Distribution</b>					
N/A	Available in person at various locations and online.	Available in person at designated permit issuing stations and online.	Same as alternative C.	Same as alternative C.	Available in person at designated NPS permit issuing stations.
<b>Permit Issuance Requirements</b>					
N/A	ORV owner must sign permit to acknowledge understanding of the rules and must carry permit when beach driving during the restricted period.	ORV owners must complete a short education program in person or online and pass a basic knowledge test. Owners would sign for their permits to acknowledge understanding of the rules and regulations governing ORV use at the Seashore.	ORV owners must read an information brochure and sign the permit to acknowledge understanding of the rules and regulations governing ORV use at the Seashore.	Same as alternative C.	ORV owners must complete a short education program in person and sign the permit to acknowledge understanding of the rules and regulations governing ORV use at the Seashore.
<b>Permit Types</b>					
N/A	Night-driving permit for Sep 16 to Nov 15.	Annual ORV permits would be valid for 12 months from date of purchase.	Annual ORV permits would be valid for the calendar year.	Weekly (7-day) and annual (12-month) ORV permits would be valid from date of purchase. Permits would include night-driving component for September 16 to November 15. In addition, a separate permit would be required for the following activities: <ul style="list-style-type: none"> <li>• Park-and-stay overnight.</li> <li>• Self-contained vehicle (SCV) camping.</li> </ul>	7-day ORV permits would be valid from date of purchase. Annual ORV permits would be valid for the calendar year. Permits would include night-driving component for September 16 to November 15.
<b>Permit Number Limits</b>					
N/A	No limit on night-driving permits.	No limit on ORV permits.	Same as alternative C.	Same as alternative C, except: <ul style="list-style-type: none"> <li>• Use limits would be established for park-and-stay and SCV camping.</li> <li>• Use limits would be subject to periodic review.</li> </ul>	Same as alternative C.

Alternative A: No Action— Continuation of Management under the Interim Strategy	Alternative B: No Action— Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Permit Fees</b>					
N/A	None	ORV permit fee would be based on cost recovery as described in NPS Director’s Order and Reference Manual 53.	Same as alternative C, except: <ul style="list-style-type: none"> <li>Amount of fee would be lower than alternative C due to decreased management costs under this alternative.</li> </ul>	Same as alternative C, except: <ul style="list-style-type: none"> <li>Fee for weekly ORV permit would be less than fee for annual permit.</li> <li>Fees for park-and-stay and SCV permits would be determined separately.</li> </ul>	Same as alternative C, except: <ul style="list-style-type: none"> <li>Fee for 7-day ORV permit would be less than fee for annual permit.</li> </ul>
<b>Permit Form</b>					
N/A	Night-driving permit is an informational brochure that the user signs and places on dash of vehicle.	ORV permit would be affixed to vehicle in a manner approved by the NPS.	Same as alternative C.	Same as alternative C.	Same as alternative C.
<b>Permit Revocation</b>					
N/A	Night-driving permit may be revoked for violation of applicable park regulations or terms and conditions of the permit.	ORV permit may be revoked for violation of applicable park regulations or terms and conditions of the permit.	Same as alternative C.	Same as alternative C.	Same as alternative C.
<b>Beach Parking</b>					
Parking within routes is allowed in any configuration, as long as parked vehicles do not obstruct traffic.	Same as alternative A.	Same as alternative A.	Parking within ORV routes is allowed, but only one vehicle deep. Stacking of vehicles in more than one row would be prohibited.	Same as alternative A.	Parking within ORV routes is allowed, but only one vehicle deep, as long as vehicles do not obstruct two-way traffic. Stacking of vehicles in more than one row would be prohibited.
<b>Vehicle Carrying Capacity Determination</b>					
Vehicle carrying capacity would not be determined.	Same as alternative A.	Carrying capacity would be a “peak use limit” determined for all areas based on the linear feet of beachfront and the following physical space requirements (“mile” refers to miles of beach open to ORV use): <p><b>Bodie Island District:</b></p> <ul style="list-style-type: none"> <li>260 vehicles/mile (20 feet/vehicle).</li> </ul> <p><b>Hatteras Island District:</b></p> <ul style="list-style-type: none"> <li>260 vehicles/mile (20 feet/vehicle).</li> </ul> <p><b>Ocracoke Island District:</b></p> <ul style="list-style-type: none"> <li>175 vehicles/mile (30 feet/vehicle).</li> </ul> Temporary exceptions to carrying-capacity limits may be approved for short-term events operating under a special use permit. Carrying-capacity criteria would be subject to periodic review.	Carrying capacity would be addressed solely by the beach parking restriction described in the row above.	Same as alternative C, except: <p><b>Hatteras Island District:</b></p> <ul style="list-style-type: none"> <li>Cape Point: 400 vehicles allowed within a 1 mile area centered on Cape Point.</li> </ul>	The maximum number of vehicles allowed on any particular ORV route is the linear distance of the route divided by 6 meters (20 feet) per vehicle (i.e., the equivalent of 260 vehicles per mile).

Alternative A: No Action— Continuation of Management under the Interim Strategy	Alternative B: No Action— Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>ORV Characteristic Requirements</b>					
All vehicles operating in all areas of the Seashore must have valid vehicle registration, insurance, and license plate. Vehicles must be street legal. All-terrain vehicles (ATVs) are prohibited from beach driving.	Same as alternative A.	Off-road Vehicle characteristics: <ul style="list-style-type: none"> <li>All vehicles must be registered, licensed, and insured for highway use and must comply with state inspection regulations within the state, country, or province where the vehicle is registered</li> <li>Four-wheel-drive vehicles are recommended.</li> <li>Two-wheel-drive vehicles are allowed.</li> <li>Motorcycles and ATVs are prohibited.</li> <li>There is a three-axle maximum for vehicles (this is the axle maximum for the powered vehicle only and does not include the additional number of axles on towed trailers).</li> <li>Any trailers are limited to no more than two axles.</li> <li>The maximum vehicle length is 30 feet (this is the maximum length for the powered vehicle and does not include the additional length of a towed trailer).</li> <li>Tires must be U.S. Dept. of Transportation-listed or approved.</li> </ul>	Same as alternative C.	Same as alternative C, except: <ul style="list-style-type: none"> <li>Motorcycles would be prohibited on ocean beaches, but allowed on soundside access areas where ORVs are allowed.</li> </ul>	Off-road vehicle characteristics: <ul style="list-style-type: none"> <li>All vehicles must be registered, licensed, and insured for highway use and must comply with state inspection regulations within the state, country, or province where the vehicle is registered.</li> <li>Four-wheel-drive vehicles are recommended.</li> <li>Two-wheel-drive vehicles are allowed.</li> <li>Motorcycles, ATVs, and UTVs are prohibited.</li> <li>The vehicle must have no more than two axles.</li> <li>Towed boat trailers are allowed and must have no more than two axles. Travel trailers (i.e., camping trailers) are prohibited.</li> <li>Vehicle tires must be U.S. Department of Transportation-listed or approved.</li> </ul>
<b>Equipment Requirements</b>					
None	Same as alternative A.	Equipment requirements: <ul style="list-style-type: none"> <li>All vehicles shall contain a low-pressure tire gauge, shovel, jack, and jack stand.</li> <li>A full-sized spare tire, first-aid kit, fire extinguisher, trash bag or container, flashlight (if night driving), and tow strap are recommended.</li> </ul>	Same as alternative C.	Same as alternative C.	Same as alternative C.
<b>Tire Pressure</b>					
Recommend air down of tires before driving on the beach.	Same as alternative A.	When driving on designated routes, tire pressure must be lowered sufficiently to maintain adequate traction within the posted speed limit. Tire pressure of 20 psi is <i>recommended</i> for most vehicles. The softer the sand, the lower the pressure needed. Re-inflate tires to normal pressure as soon as possible after vehicle returns to paved roads.	<b>Same as alternative C.</b>	<b>Same as alternative C.</b>	<b>Same as alternative C.</b>

<b>Resource Protection Measures</b>					
<b>Breeding Season Measures</b>					
Shorebird prenesting areas and ORV/pedestrian buffers for observed shorebird breeding behavior, sea turtle nests, and seabeach amaranth are established as described in the Interim Strategy FONSI (table 9).	Shorebird prenesting areas and ORV/pedestrian buffers for observed shorebird breeding behavior, sea turtle nests, and seabeach amaranth are established as described in the Interim Strategy FONSI (table 9), as modified by the consent decree.	Breeding Shorebird SMAs would be designated. Shorebird prenesting areas and ORV/pedestrian buffers for observed shorebird breeding behavior, sea turtle nests, and seabeach amaranth would be established as described in table 10. ML1 measures would be implemented at all locations (including those outside of SMAs), except at Bodie Island Spit, Cape Point, and South Point Ocracoke, where ML2 measures would be implemented. Designated SMAs would be subject to periodic review.	Same as alternative C, except: <ul style="list-style-type: none"> <li>ML1 would be implemented at all locations.</li> </ul>	Same as alternative C, except: <ul style="list-style-type: none"> <li>ML2 areas at Bodie Island Spit, Cape Point, and South Point Ocracoke would include an ORV pass-through zone, using standard buffer distances as described in table 10.</li> </ul>	Prenesting areas and buffers would be established as described in table 10-1. Pedestrian shoreline access below the high tide line would be permitted in front of (i.e., seaward of) prenesting areas until breeding activity is observed, then standard buffers for breeding activity would apply. The NPS retains discretion at all times to enforce more protective closures or take other measures, if considered necessary, consistent with its obligations under the law.
<b>Nonbreeding Season Measures</b>					
As described in the Interim Strategy FONSI: Suitable interior habitats at spits and at Cape Point are closed year-round to all recreational users to provide for resting and foraging for shorebirds. Suitable habitats include ephemeral ponds and moist flats at Cape Point, Hatteras Spit, Ocracoke, and Bodie Island Spit. Actual locations of suitable foraging and resting habitat may change periodically due to natural processes and are determined based on annual habitat assessment and monitoring.	Same as alternative A.	Nonbreeding Shorebird SMAs would be established at the points and spits based on an annual habitat assessment. In addition, year-round VFAs along the ocean shoreline outside of the villages, as identified in table 7, would be managed as Nonbreeding Shorebird SMAs with recreational activity restrictions as described in table 10. Designated SMAs would be subject to periodic review.	Same as alternative C.	Same as alternative C.	VFAs throughout the Seashore would provide relatively less disturbed foraging, resting, and roosting habitat for migrating and wintering birds. These areas would be managed as described in table 10-1.

<b>Vegetation</b>					
ORV use is generally restricted to minimize impacts.	Same as alternative A.	ORV use would be restricted or prohibited in locations where ORV use is causing unacceptable impacts to vegetation.	Same as alternative C.	Same as alternative C.	Same as alternative C.

**TABLE 9. SPECIES OBSERVATION AND MANAGEMENT UNDER THE INTERIM PROTECTED SPECIES MANAGEMENT STRATEGY, CONSENT DECREE, AND MODIFIED CONSENT DECREE**

Note: This table represents actions from the FONSI for the Interim Protected Species Management Strategy (alternative A). Additions in bold, italic font indicate changes made by the consent decree or modified consent decree as indicated (alternative B).

SPECIES OBSERVATION ACTIVITY	
<b>Survey Time and Frequency</b> <b>Prenesting</b>	<p>Piping plover: March 15 – March 31 survey recent breeding areas at Bodie Island Spit, Cape Point and South Beach, Hatteras Spit, and the northern and southern ends of Ocracoke one time per week. April 1 – June 15 survey recent breeding areas at Bodie Island Spit, Cape Point and South Beach, Hatteras Spit, and the northern and southern ends of Ocracoke three times per week (or every other day) and potential new habitat two times per week. Survey for Wilson's plover during piping plover surveys. American oystercatcher: March 15 – June 15 survey recent breeding areas two times per week. Colonial waterbirds: May 1 – June 15 survey recent breeding areas two times per week.</p> <p><b>CONSENT DECREE</b></p> <ul style="list-style-type: none"> <li>• <b><i>Survey Cape Point, South Beach, Hatteras Spit, North Ocracoke, and Ocracoke South Point at least once every two days from March 15 to April 15, and daily from April 16 to July 15, to determine if any birds are exhibiting prenesting and/or breeding behavior. The NPS shall monitor Bodie Island Spit at least daily from March 15 to July 15.</i></b></li> </ul>
<b>Survey Time and Frequency</b> <b>Life Stages</b>	<p><u>Courtship/Mating:</u> If species are observed exhibiting territorial or courtship behavior during two consecutive surveys in historic habitat, observe three times per week. If scrapes or eggs are observed, survey three times per week. Survey potential new habitat two times per week.</p> <p><u>Nesting:</u> Piping plover: Observe nests from a distance that does not disturb the birds, based on professional judgment, one time daily. Approach nests once per week to observe and record data. American oystercatcher and colonial waterbirds: Observe nests at least three times per week. Wilson's plover: Observe nests incidental to piping plover monitoring.</p> <p><u>Unfledged Chicks:</u> Piping plover: During the first week, observe continually during daylight hours. After the first week, if the closure is reduced or remains the same size, keep continuous observation. If the closure is enlarged, observe once daily. American oystercatcher: Observe once daily. Colonial waterbirds: Observe broods at one-day to two-day intervals and record data. Wilson's plover: Observe broods incidental to piping plover monitoring. All Species: When broods are mobile, provide more frequent observation and enforcement presence. All observations end when all chicks have fledged.</p> <p><u>Nonbreeding/Wintering:</u> Piping plover: As provided in the USFWS Amended Biological Opinion (2007) (attachment 1 to the FONSI), the NPS will monitor the presence, abundance, and behavior of migrating and wintering piping plovers from August 1 – March 31 of each year. At each session, specific observations include vehicle, pedestrian, and pet tracks in posted habitat; any signs of predators, including species; specific management measures in place at the time of the observation; observed behaviors; and reactions to disturbance by pedestrians, pets, or vehicles. American oystercatcher, red knot, Wilson's plover: Survey with piping plover. Colonial waterbirds: Winter/Nonbreeding habitat not surveyed.</p>
<b>Data Collected</b>	<p>Piping plover: Use GPS to document breeding areas and nest locations. Record locations where territorial/courtship behavior occurs. Record presence and abundance of birds. American oystercatcher and colonial waterbirds: Use GPS to document nest and colony locations. Record presence and abundance of prenesting birds.</p>
<b>Sea Turtles</b>	
<b>Survey Time and Frequency</b>	<p>May 1 – September 15 Conduct daily morning surveys by ATV and some ORVs for crawls and nests on all beaches before onset of heavy public ORV use. Daily surveys for nests end September 15. Periodic monitoring (e.g., every two to three days) for unknown nesting and emerging hatchlings will continue, especially in areas of high visitation, September 16 – November 15. Monitoring will also occur for post-hatchling washbacks during periods when there are large quantities of seaweed washed ashore or following severe storm events. Nest observations stop when all nests have hatched or excavation indicates that the nest was not viable. Once a light filter fence is installed, monitor nests daily for signs of hatchling emergence.</p>

SPECIES OBSERVATION ACTIVITY	
<b>Data Collected</b>	<p>Follow the North Carolina Wildlife Resources Commission Handbook and record:</p> <ul style="list-style-type: none"> <li>• Turtle species</li> <li>• Nest vs. false crawl</li> <li>• Location (physical description and GPS location)</li> <li>• -If nest needs to be relocated and, if so, why and where (new physical description and GPS location), number of eggs relocated, and time of day</li> <li>• Necessary protective measures for nest and hatchlings</li> <li>• Information regarding any post hatching nest excavation and analysis</li> </ul> <p>Examine all nests after hatching to determine productivity rates. Excavate nests at a minimum of 72 hours after hatching event. In cases where hatching events or dates were unknown, unearth nest cavities 80–90 days after the lay date.</p>
<b>Seabeach Amaranth</b>	
<b>Survey Time and Frequency</b>	<p>April 1 During bird and turtle surveys, note any seedlings or plants and record location.</p> <p>August Annual survey of potential habitat (some bird closure areas may not be surveyed due to potential to disturb nesting birds).</p> <p>April – September Before opening any species closure or identifying alternate ORV corridors, survey for seedling/plants.</p> <p>End observations when all plants have died back.</p>
<b>Data Collected</b>	Record location of all individual plants or plant clusters using a GPS and note if the plant is located in an area open or closed to recreational use.
<b>Essential Vehicle Use</b>	
<b>Bird Surveys</b>	Piping plover: During bird surveys, NPS vehicles will remain outside of established resources closures.
SPECIES MANAGEMENT ACTIVITY	
<b>Closures/Buffers</b>	<p><u>Prenesting:</u></p> <p>American oystercatcher: March 15 Activate closures if a territory is established or a nest located. Closures removed when areas have been abandoned for a two-week period.</p> <p>Piping plover: April 1 In February or March of each year, NPS natural resource staff to conduct an annual assessment of piping plover breeding habitat to plan prenesting closures in recent breeding areas that are adapted to current habitat and physiographic conditions. Close recent breeding areas by posting symbolic fencing by April 1. Remove closures if no bird activity is seen by July 15 or when area has been abandoned for a two-week period, whichever comes later.</p> <p>Colonial waterbirds: May 1 Activate closures if a territory is established or a nest located. Closures removed when areas have been abandoned for a two-week period.</p> <p>All Species: Designate a 100-foot-wide ORV and pedestrian corridor. Outside of ORV corridor, prohibit pedestrian access to breeding areas beyond the symbolic fencing. Delineate the corridor with posts placed up to 100 feet above the high tide line. In areas of reduced corridor width (i.e., narrower than 100 feet), post a reduced speed limit of 10 mph.</p> <p><b>CONSENT DECREE</b></p> <ul style="list-style-type: none"> <li>• <i>All-species: Prenesting areas established on Bodie Island Spit, Cape Point, South Beach, Hatteras Spit, North Ocracoke, and Ocracoke South Point. The prenesting areas shall remain in place until the later of July 15 or two weeks after the last tern, black skimmer, American oystercatcher, piping plover, or Wilson's plover chick within the area has fledged, as determined by two consecutive monitoring events. Prenesting areas would be delineated to incorporate to the maximum extent the areas delineated in the 2008 prenesting closure maps and would include to the maximum extent possible the soundside intertidal zone, areas of moist soil habitat, ocean backshore, dunes, dry sand flats, overwashes, blowouts, and areas of the ocean tidal zone consistent with these areas.</i></li> <li>• <i>If NPS observes prenesting and/or breeding behavior of colonial waterbirds, piping plovers, or American oystercatchers, NPS shall establish the appropriate buffer as quickly as possible, but always within 8 daylight hours.</i></li> </ul>

SPECIES MANAGEMENT ACTIVITY	
<b>Closures/Buffers (continued)</b>	<p><u>Courtship/Mating:</u>  Piping plover: If courtship or copulations are observed outside of existing closures on two consecutive survey days, establish or expand buffer to ensure 150-foot buffer for the observed birds.  If additional closures are created around courtship/mating areas, adjust the ORV corridor whenever possible to allow vehicle passage. Allow management to be responsive to individual bird behavior when determining adequacy of closure size.  American oystercatcher and colonial waterbirds: If territorial or courting birds are observed outside of existing closures, based on bird behavior and suitable habitat, expand buffers to accommodate the birds. Provide ORV/pedestrian corridor above the high tide line.</p> <p><b>CONSENT DECREE</b></p> <ul style="list-style-type: none"> <li>• <b><i>Piping Plover: 50-meter buffer.</i></b></li> <li>• <b><i>Least Tern: 100-meter buffer.</i></b></li> <li>• <b><i>Other Colonial Waterbirds: 200-meter buffer.</i></b></li> <li>• <b><i>American Oystercatcher: 150-meter buffer.</i></b></li> <li>• <b><i>When multiple species present, greatest applicable buffer distance shall be used.</i></b></li> </ul>
	<p><u>Nesting:</u>  Piping plover: Establish 150-foot buffer/closure around piping plover nests occurring outside existing closures. Expand closures, if necessary, using flexible increments dependent on observed bird behavior. When resource closures are created around nests, adjust the ORV corridor whenever possible to allow vehicle passage. Reduce the width of the ORV corridor if necessary. In areas in which the buffer zone would eliminate the ORV corridor, identify alternate ORV routes if available or provide a bypass (see "Short-term Bypass Route Criteria" on page 11 of the FONSI) if possible.  American oystercatcher: Establish buffer/closure based on adult's reaction to human disturbance. Closures vary in size dependent on best professional judgment. When resource closures are created around nests, adjust the ORV corridor whenever possible to allow ORV passage. Reduce width of ORV corridor if necessary. In areas in which the buffer zone would eliminate the ORV corridor, identify alternate ORV routes if available, or provide a bypass (see "Short-term Bypass Route Criteria" on page 11 of the FONSI) if possible. Allow observations to be responsive to individuality in bird behavior when determining adequate size of closure zones around nests.  Colonial waterbirds: Establish a buffer/closure of 150 feet to 300 feet around the nest or colony based on observed bird behavior, while maintaining ORV/pedestrian corridor. If the buffer and the corridor overlap each other, then staff will reduce corridor width if necessary. In areas in which the buffer zone would eliminate the ORV corridor, identify alternate ORV routes if available, or provide a bypass (see "Short-term Bypass Route Criteria" on page 11 of the FONSI) if possible. Allow observations to be responsive to individuality in bird behavior when determining adequate size of closure zones around nests.  Reduced width of ORV/pedestrian corridors for American oystercatcher and colonial waterbirds will be approached as a research opportunity to gather data useful for the long-term ORV management plan/EIS to test for the distance at which vehicle disturbance to nesting American oystercatcher and colonial waterbirds occurs.  All species:  Allow observations to be responsive to individuality in bird behavior when determining adequate size of closure zones around nests.  If nest is lost, buffers remain in place 2–3 weeks after nest is lost to determine if pair will re-nest, if no other species nesting in area.</p> <p><b>CONSENT DECREE</b></p> <ul style="list-style-type: none"> <li>• <b><i>Piping Plover: 50-meter buffer.</i></b></li> <li>• <b><i>Least Tern: 100-meter buffer.</i></b></li> <li>• <b><i>Other Colonial Waterbirds: 200-meter buffer.</i></b></li> <li>• <b><i>American Oystercatcher: 150-meter buffer.</i></b></li> <li>• <b><i>When multiple species present, greatest applicable buffer distance shall be used.</i></b></li> <li>• <b><i>Upon discovery of an active nest outside an existing closure, protective measures shall be taken immediately to close and establish the buffers described above. Symbolic fencing with the applicable buffer distances stated above shall be installed as soon as NPS staff can reasonably be mobilized to erect the fencing, but always within 6 daylight hours.</i></b></li> </ul>
	<p><u>Adult Foraging:</u>  Piping plover: For adults foraging outside of a closure on two consecutive surveys, expand buffer to include foraging site. These closures are intended to provide foraging opportunities close to breeding sites.  Colonial waterbirds, American oystercatcher, and Wilson's plover: No additional buffers/closures.</p> <p><b>CONSENT DECREE</b></p> <ul style="list-style-type: none"> <li>• <b><i>If no piping plover are observed utilizing such a foraging closure over a two-week period of time, the closure will be removed.</i></b></li> </ul>

SPECIES MANAGEMENT ACTIVITY	
Closures/Buffers (continued)	<p><u>Unfledged Chicks:</u></p> <p>Piping plover: Establish a minimum 600-foot buffer on either side of brood based on observation of bird behavior and terrain conditions at site. Based on observed behavior, buffer area may require expansion up to 3,000 feet if chicks are highly mobile. Based on observed behavior (i.e., mobility of the brood) and the capability to continually observe mobility and behavior, buffer zone can be reduced after the first week to no less than 300 feet, but may require expansion up to 3,000 feet if chicks are highly mobile. Buffer moves with chicks. Close bypass route at night if buffer zone is less than 600 feet (as identified on p. 8 of the USFWS Amended Biological Opinion (2007) [attachment 1 to the FONSI]).</p> <p>When resource closures are created around broods, adjust the ORV corridor whenever possible to allow vehicle passage. Reduce ORV corridor if necessary. In areas in which the buffer zone would eliminate the ORV corridor identify alternate ORV routes if available. If there are no alternate ORV routes, then if possible establish a bypass (see "Short-term Bypass Route Criteria" on page 11 of the FONSI). Close beach to recreation access down to the waterline, if necessary, to allow chicks access to foraging areas.</p> <p>American oystercatcher: Establish 150-foot to 300-foot buffer zone when unfledged chicks are present. Adjust buffer zone as needed when chicks are mobile. Provide alternate ORV/pedestrian access route or bypass to open areas beyond the closure, if possible.</p> <p>Colonial waterbirds: Establish 150-foot to 300-foot buffer zone when unfledged chicks present. Adjust buffer zone as needed when chicks are mobile. Provide alternate ORV/pedestrian access route or bypass to open areas beyond the closure, if possible.</p> <p>For all species: Allow observations to be responsive to individuality in bird behavior when determining adequate size of closure zones around broods.</p> <p>Reopen 100-foot-wide ORV corridor in recent or current nesting areas after chicks fledge. Areas outside of corridor, including the upper beach remain available for protected species use. Re-establish 150-foot ORV corridor after August 31.</p> <p><b>CONSENT DECREE</b></p> <ul style="list-style-type: none"> <li>• <i>Piping Plover: 1,000-meter buffer, although it would be reduced to 300 meters for pedestrians during daylight hours only. Two-weeks after hatching, the NPS may allow ORV access within the 1,000-meter buffer down to 300 meters, although the NPS may re-establish the 1,000-meter buffer based on plover movement or behavior. Vehicles may be allowed to pass through portions of the protected area, where the protected area is considered by NPS natural resource management staff to be inaccessible to piping plover chicks because of steep topography, dense vegetation, or other naturally occurring obstacles. All of the ocean beach at Cape Point, South Beach, and North Ocracoke and all of the bayshore and ocean beach at Bodie Island Spit and Ocracoke South Point will be considered accessible to piping plover chicks in these areas. Within the 1,000-meter piping plover unfledged chick buffer at Hatteras Spit, all of the ocean beach and that part of the bayshore beach at the overwash fans and from the inlet east to a point 200 meters east of the point where the Spur Road from the Pole Road meets the bayshore will be considered accessible to piping plover chicks in these areas.</i></li> <li>• <i>All other species: 200-meter buffer.</i></li> <li>• <i>Locations of buffers are adjusted to accommodate chick movement. The NPS retains discretion to enforce greater restrictions as necessary to protect the species.</i></li> <li>• <i>When multiple species present, greatest applicable buffer distance shall be used.</i></li> <li>• <i>Upon discovery of chicks outside an existing closure, protective measures shall be taken immediately to close and establish the buffers described above. Symbolic fencing with the applicable buffer distances stated above shall be installed as soon as NPS staff can reasonably be mobilized to erect the fencing, but always within 6 daylight hours.</i></li> </ul>
Disturbance from ORVs or Pedestrians	<p><b>CONSENT DECREE</b></p> <ul style="list-style-type: none"> <li>• <i>If NPS staff observes disturbance from ORVs and/or pedestrians, buffers would be expanded in 50-meter increments until no disturbance occurs. If a deliberate violation occurs that disturbs wildlife or vandalizes nests or fencing, the buffer would be expanded by 50 meters on the first offense. If there are multiple occurrences in the same area, the buffer would be expanded by 100 meters and 500 meters for the second and third violations, respectively.</i></li> </ul> <p><b>MODIFIED CONSENT DECREE</b></p> <ul style="list-style-type: none"> <li>• <i>If a violator is apprehended, the NPS would not be required to institute expanded buffers. If the buffer has been expanded and then the violator is caught, the NPS can retract the expansion.</i></li> </ul>
Non Breeding/Wintering Closures	<p>For piping plover: Suitable interior habitats at spits and at Cape Point closed year-round to all recreational users to provide for resting and foraging for all species. For example, at present, such suitable habitats include ephemeral ponds and moist flats at Cape Point, Hatteras Spit, Ocracoke, and Bodie Island Spit. Actual locations of suitable foraging and resting habitat may change periodically due to natural processes.</p>

SPECIES MANAGEMENT ACTIVITY	
<b>Sea Turtles</b>	
<b>Nest Closures/Buffers</b>	<p>Establish a buffer approximately 30 feet by 30 feet with symbolic fencing and signage around nest.</p> <p>Approximately 50–55 days into incubation, closures expanded to the surf line. The width of the closure based on the type and level of use in the area of the beach where the nest was laid:</p> <ol style="list-style-type: none"> <li>VFAs with little or no pedestrian traffic – 75 feet wide (total width);</li> <li>villages or other areas with high levels of day use – 150 feet wide (total width);</li> <li>areas with ORV traffic – 350 feet wide (total width).</li> </ol> <p>Opposite the surf line on the upper end of the closure, the closed area expanded to 50 feet where possible, but no less than 30 feet duneward from the nest. Traffic detours behind the nest area clearly marked with signs and reflective arrows.</p> <p>Where present within closure, vehicle tracks manually smoothed with rakes or a steel mat attached to an ATV, so as not to impede hatchlings attempting to reach the surf.</p> <p>Use light filtering fence behind nests nearing hatch dates to block light pollution from the villages and vehicles operating on the beach after dark.</p> <p><b>CONSENT DECREE</b></p> <ul style="list-style-type: none"> <li>After September 15 all remaining unhatched turtle nests, once they reach their hatch window, shall be protected by full beach closures.</li> </ul> <p><b>MODIFIED CONSENT DECREE</b></p> <ul style="list-style-type: none"> <li>After September 15, all unhatched turtle nests would only require full beach closures from sunset until 6:00 a.m. instead of 24 hours a day.</li> </ul>
<b>Nest Relocation</b>	<p>When a nest is found, staff assesses need for nest relocation and follows relocation guidance identified in the NCWRC handbook.</p> <p>If it is determined the nest will not be relocated, it will be immediately protected with a symbolic fence measuring approximately 30 feet by 30 feet and signage.</p> <p>If a nest is threatened by a storm event, the NPS will consult NCWRC to determine appropriate action.</p>
<b>Light Management</b>	<p>Establish turtle friendly lighting standards for all Seashore (NPS) structures.</p> <p>Encourage concessioners to install turtle friendly lighting.</p>
<b>Research</b>	<p>Support research efforts looking at the sex ratios of turtles.</p>
<b>Seabeach Amaranth (SBA)</b>	
<b>Buffers</b>	<p>April 15 – November 30</p> <p>If a plant/seedling is found outside of an existing closure, the Seashore will erect symbolic fencing with signage creating a 30-foot by 30-foot buffer around the plant. If plants are located next to each other, the area will be expanded to create one enclosure protecting several plants.</p> <p>If a SBA is found during the survey prior to reopening a bird closure to ORV and pedestrian use, the Seashore will protect the SBA as described above and reopen the areas of the bird closure where no plants exist.</p> <p>Areas reopened if no plants are present by September 1. Where plants occur, the closed areas will be reopened after the plants have died.</p>
<b>Predator Management</b>	<p>Trappers will target red and gray fox, raccoons, cats and other predators for removal.</p> <p>Piping plover: Nests surveyed to count eggs and look for predator tracks.</p> <p>As applicable, predator exclosures are erected when nest found with eggs.</p> <p>American oystercatcher and colonial waterbirds: Nests surveyed to count eggs and look for predator tracks.</p> <p>Sea Turtle: Nests surveyed to count eggs and look for predator tracks. Predator exclosures may be placed over nests if predator tracks or nest predation is evident.</p> <p>SBA: No predator management.</p>
<b>Conservation Measures</b>	<p>Conservation measures are discretionary activities intended to minimize or avoid adverse effects of an action on listed species or critical habitat, to help implement recovery plans, or to develop information. Conservation measures outlined in the USFWS Amended Biological Opinion (2007) (attachment 1 to the FONSI) will be considered for implementation. The Seashore will notify the USFWS when any of these conservation measures are implemented.</p>

**TABLE 10. SPECIES MANAGEMENT STRATEGIES FOR ALTERNATIVES C, D, AND E**

DEFINITIONS			
<p><b>Breeding behavior:</b> Shorebird behavior that includes, but is not limited to, courtship, mating, scraping, confirmed scrapes, and other breeding or nest-building activities. The terms breeding behavior and breeding activity are used synonymously.</p> <p><b>Human disturbance:</b> Any human activity that changes the contemporaneous behavior of one or more individuals of breeding, nesting, foraging, or roosting colonial waterbirds, piping plover, Wilson’s plover, or American oystercatcher. Behaviors indicating disturbance include defensive displays; alarm calls; flushing or leaving a nest or feeding area; and diving or mobbing pedestrians, dogs, or vehicles.</p> <p><b>Periodic review:</b> A systematic review of data, habitat conditions, and other information to be conducted by the NPS every 5 years, after storms or events that Seashore management determines to be a major modification of habitat quantity or quality, or after a significant change in protected species status (e.g., listing or de-listing), in order to evaluate the effectiveness of management actions in making progress toward the accomplishment of stated objectives. Periodic review could result in changes to the management actions in order to improve effectiveness. When desired future conditions for resources are met or exceeded, periodic review and adaptive management may allow for more flexible management of recreational use, provided adverse impacts of such use are effectively managed and wildlife populations remained stable. Where progress is not being made toward goals, periodic review and adaptive management may result in <u>increased</u> restrictions on recreational use.</p> <p><b>Prenesting closure:</b> A kind of resource closure in which an area of suitable habitat is proactively closed to ORVs and pedestrians at the start of the shorebird breeding season to provide undisturbed habitat for bird breeding activities to occur.</p> <p><b>Research area:</b> Area of suitable habitat set aside on a temporary or long-term basis (such as a study site or control plot) as part of a research project authorized by NPS under a research permit.</p> <p><b>Resource closure:</b> Any area posted as closed to all public entry in order to protect wildlife, such as breeding and foraging shorebirds and bird and turtle nests, or vegetation from human disturbance.</p> <p><b>Species Management Area (SMA):</b> Area of suitable habitat that has had concentrated and recurring use by multiple individuals and/or multiple species of protected shorebirds during the breeding season or nonbreeding season, or concentrations of seabeach amaranth specimens, in more than one (i.e., two or more) of the past 5 years and is managed to reduce or minimize human disturbance. Currently designated SMAs are listed at the end of this table. SMAs will be re-evaluated and re-designated every 5 years, or after storms or events that Seashore management determines to be a major modification of habitat quantity or quality, or if necessitated by a significant change in protected species status (e.g., listing or de-listing), as part of the periodic review process described at the end of this table.</p>			
<ul style="list-style-type: none"> <li>• <b>Breeding Shorebird and Seabeach Amaranth SMA:</b> Area of suitable breeding habitat that has had multiple nests of individuals and/or multiple species of protected shorebirds, or concentrations of seabeach amaranth specimens, in more than 1 (i.e., 2 or more) of the past 5 years and is managed to minimize human disturbance during the breeding season. Focal species for Breeding Shorebird SMAs include piping plover, Wilson’s plover, American oystercatcher, least tern, common tern, gull-billed tern, and black skimmer; however, there will be ongoing evaluation of the breeding shorebird species addressed by this plan, as part of the periodic review process described at the end of this table. The following areas have been initially designated as Breeding Shorebird SMAs:</li> <li>• <b>Bodie Island Spit:</b> 0.2 mile south of ramp 4 to inlet</li> <li>• Ramp 27 to ramp 30</li> <li>• New ramp 32.5 to ramp 34</li> <li>• Approximately 1.7 miles south of ramp 38 to north boundary of Buxton</li> <li>• Cape Point: 0.2 mile south of ramp 44 to ramp 45</li> <li>• South Beach: ramp 45 to new ramp 47</li> <li>• Hatteras Inlet Spit: Ocean shoreline south of Pole Road to soundside of inlet</li> <li>• North Ocracoke Spit: Inlet to 0.25 mile northeast of ramp 59</li> <li>• 0.5 mile southwest of ramp 68 to 1.2 miles north of ramp 70</li> <li>• South Point Ocracoke: 0.5 mile southwest of ramp 72 to inlet</li> <li>• <b>Nonbreeding Shorebird SMA:</b> Area of suitable nonbreeding habitat that has had concentrated foraging by migrating/wintering shorebirds in more than 1 (i.e., 2 or more) of the past 5 years and is managed to reduce human disturbance during the nonbreeding season. This may include portions of breeding SMAs that provide suitable nonbreeding habitat during periods of overlap between the breeding and migrating season and designated VFAs that are set aside to provide pedestrians with the opportunity for a natural beach experience.</li> </ul> <p><b>Management Level 1 (ML1):</b> An approach to shorebird protection during the breeding season that will use larger, longer-lasting buffers with less monitoring to reduce the need for more frequent monitoring and fencing changes.</p> <p><b>Management Level 2 (ML2):</b> An approach to shorebird protection during the breeding season that will use smaller buffers and will require more frequent monitoring and fencing changes when an ORV or pedestrian access corridor is open at designated locations during the breeding season.</p>			
Management Activity	Shorebirds		
	Piping Plover	American Oystercatcher and Wilson’s Plover	Colonial Waterbirds, including Least Terns, Common Terns, Gull-Billed Terns, and Black Skimmers
Prenesting Surveys	By Mar 1: NPS staff will evaluate all potential breeding habitat and recommend piping plover prenesting closures based on that evaluation.  Mar 15 to Jul 15: Prenesting closures will be surveyed three times per week. Outside of prenesting closures, suitable habitat will be surveyed twice per week, increasing to three times per week once birds are present.	Mar 15 to Jul 15: Prenesting closures will be surveyed three times per week.  Outside of prenesting closures, suitable habitat will be surveyed twice per week, increasing to three times per week once breeding pairs are present.	May 1 to Jul 15: Prenesting closures will be surveyed three times per week.  Outside of prenesting closures, suitable habitat will be surveyed twice per week, increasing to three times per week once breeding pairs are present.

Table 10. Species Management Strategies for Alternatives C, D, and E

Management Activity	Shorebirds		
	Piping Plover	American Oystercatcher and Wilson's Plover	Colonial Waterbirds, including Least Terns, Common Terns, Gull-Billed Terns, and Black Skimmers
<b>Prenesting Closures</b>	<p><b>All species:</b> All designated Breeding Shorebird SMAs will be posted as prenesting closures using symbolic fencing by <b>Mar 15</b> at sites involving piping plover, Wilson's plover, and/or American oystercatcher; and by <b>Apr 15</b> at sites involving only colonial waterbirds. The NPS will determine the configuration of specific prenesting closures based on an annual habitat assessment. Prenesting closures would be adjusted to the configuration of the Nonbreeding Shorebird SMAs for the respective sites (as described later in this table) if no breeding activity is seen in the area by <b>Jul 31</b>, or 2 weeks after all chicks have fledged, whichever comes later. Prenesting closures will not be modified in cases where the beach erodes into the buffered habitat. ORVs, pedestrians, and pets are prohibited within all resource closures, including prenesting closures.</p> <p><b>ML1:</b> SMAs managed using ML1 measures would not allow ORV or pedestrian access when prenesting closures are in effect. Areas outside of SMAs would be managed under ML1 measures.</p> <p><b>ML2:</b> The Bodie Island Spit, Cape Point, and South Point Ocracoke SMAs would be managed using ML2 measures in action alternatives C, E, and F. Once prenesting closures are implemented at these sites, a narrow ORV access corridor (where ORV use is permitted) or a pedestrian access corridor (where ORV use is not permitted) would be established. Upon the first observation of breeding activity, the standard buffers (please refer to table 11, Shorebird/Waterbird Buffer Summary) will apply, which depending upon the circumstances may close the access corridor. The Bodie Island Spit access corridor would follow the ocean shoreline to the inlet. The Cape Point access corridor would follow the ocean shoreline from ramp 44 south to the point, then west approximately 0.2 mile along the ocean shoreline. The South Point Ocracoke access corridor would follow the ocean shoreline south from ramp 72 to the inlet. Exact configuration of the corridor would be determined by NPS staff based on the annual habitat assessment. The ORV access corridor at ML2 sites will generally be no more than 50 meters wide above the high tide line (alternative E may include a designated pass-through zone where no stopping or recreation would be permitted in order to minimize disturbance). An ML2 pedestrian access corridor would generally be below the high tide line and would in no case be more than 10 meters above the high tide line. Pets, as well as kite flying, ball and Frisbee tossing, and similar activities, will be prohibited in the access corridors or pass-through zones (in alternative E only) while the prenesting closure is in effect.</p>		
<b>Courtship/Mating Surveys</b>	<p>Prenesting closures would be surveyed three times per week. Outside of prenesting closures, potential suitable habitat would be surveyed three times per week once breeding pairs are present.</p>		
<b>Courtship/Mating Buffers</b>	<p><b>All species:</b> The Seashore retains the discretion to expand courtship/mating buffers under ML1 and ML2 depending on staffing and bird behavior. Areas outside of SMAs would be managed under ML1 measures. In unprotected areas, a buffer will be established immediately when courtship or mating is observed. When courtship or mating is observed in the immediate vicinity of paved roads, parking lots, campgrounds, buildings, and other facilities, the NPS retains the discretion to provide resource protection to the maximum extent possible while still allowing those facilities to remain operational. The NPS shall not reduce buffers to accommodate ORV ramp access.</p>		
	<p><b>ML1/ML2:</b> If breeding activity is observed outside of an existing closure, a buffer will be established or expanded to ensure a 75-meter buffer for the observed birds.</p> <p>Buffers will be increased in 50-meter increments if human disturbance* occurs.</p> <p>Outside of prenesting areas, closures will be removed if no breeding activity is observed for a 2-week period, or when associated breeding activity has concluded.</p> <p>*Buffers are not expanded for incidental disturbance associated with required NPS protected species monitoring.</p>	<p><b>ML1:</b> If breeding activity is observed outside of an existing closure, a buffer will be established or expanded to ensure a 300-meter buffer for the observed birds.</p> <p><b>ML2:</b> If breeding activity is observed outside of an existing closure, a buffer will be established or expanded to ensure a 150-meter buffer for the observed birds.</p> <p>Buffers will be increased in 50-meter increments if human disturbance occurs.</p> <p><b>All:</b> Outside of prenesting areas, closures will be removed if no breeding activity is observed for a 2-week period, or when associated breeding activity has concluded.</p>	<p><b>ML1:</b> If scraping is observed outside an existing closure, a buffer will be established or expanded to ensure a 300-meter buffer for the observed birds.</p> <p><b>ML2:</b> If scraping is observed outside a resource closure, a 100-meter buffer will be established around the scrape location for least terns (if only least terns are present), or a 200-meter buffer when other colonial waterbird species are present. Buffers will be increased in 50-meter increments if human disturbance occurs.</p> <p><b>All:</b> Buffer establishment will be based on the location of scrape(s) and not location of copulation or "fish flashing."</p> <p>Outside of prenesting areas, buffers will be removed if no breeding activity is observed for a 2-week period, or when associated breeding activity has concluded.</p>
<b>Nest Surveys</b>	<p>A walk-through will be conducted to look for nests every 3 days. Once nests are found, nests will be observed daily from a distance that does not disturb the birds, based on professional judgment. Nests will be approached once per week to observe and record data.</p>	<p>A walk-through will be conducted to look for nests when observations suggest a nest is present.</p> <p><b>ML1:</b> Nests will be observed at least three times per week from a distance that does not disturb the birds, based on professional judgment. For incubating birds that cannot be observed from a distance, nests will be checked on a weekly basis (or as staff is available).</p> <p><b>ML2:</b> Nests will be observed daily from a distance that does not disturb the birds, based on professional judgment. For incubating birds that cannot be observed from a distance, nests will be checked every 3 days.</p>	<p>Colonies will be surveyed during the peak nesting period for each species, which generally is during the last week of May and the first week of June, but could be later, especially for black skimmers.</p> <p><b>ML1:</b> Colonies will be observed at least three times per week from a distance that does not disturb the birds. For incubating birds that cannot be observed from a distance, colonies will be checked on a weekly basis.</p> <p><b>ML2:</b> Nests will be observed daily from a distance that does not disturb the birds, based on professional judgment. For incubating birds that cannot be observed from a distance, colonies will be checked every 3 days.</p>
<b>Nest Buffers</b>	<p><b>All species:</b> The Seashore retains the discretion to expand nest buffers under ML1 and ML2 depending on staffing and bird behavior. In unprotected areas, a buffer will be established immediately when a nest with egg(s) is found. Areas outside of SMAs would be managed under ML1 measures. Prior to hatching, vehicles may pass by such areas within designated ORV access corridors that have been established along the outside edge of nesting habitat, provided that buffers adequate to prevent human disturbance are maintained. When nests or chicks occur in the immediate vicinity of paved roads, parking lots, campgrounds, buildings, and other facilities, the NPS retains the discretion to provide resource protection to the maximum extent possible while still allowing those facilities to remain operational. The NPS shall not reduce buffers to accommodate ORV ramp access. Buffers will remain in place for 2 weeks after a nest is lost to determine if pair will re-nest. Outside of prenesting areas, buffers will be removed if no breeding activity is seen in the area for 2 weeks, or 2 weeks after all chicks have fledged, whichever comes later.</p>		
	<p><b>ML1 and ML2:</b> A 75-meter buffer/closure will be established around nest(s). Buffers will be increased in 50-meter increments if human disturbance occurs.</p> <p>If a buffer falls within the intertidal zone, a full-beach closure will result.</p>	<p><b>ML1:</b> A 300-meter buffer/closure will be established around nest(s).</p> <p><b>ML2:</b> A 150-meter buffer/closure will be established around nest(s). Buffers will be increased in 50-meter increments if human disturbance occurs.</p> <p>If a buffer falls within the intertidal zone, a full-beach closure will result.</p> <p>For nests that occur inside a prenesting closure <b>and</b> require a buffer expansion of the prenesting area, the buffer expansion may be removed to the original prenesting closure after 2 weeks with no breeding activity if the nest is lost to overwash or predation.</p>	<p><b>ML1:</b> Buffers will be the same as for courtship and mating: 300 meters.</p> <p><b>ML2:</b> A 100-meter buffer/closure will be established around a least tern nest or colony. A 200-meter buffer/closure will be established around the nest or colony if any common terns, gull-billed terns, or black skimmers are present. Buffers will be increased in 50-meter increments if human disturbance occurs.</p> <p>If a buffer falls within the intertidal zone, a full-beach closure will result.</p> <p>For a colony that occurs inside a prenesting closure <b>and</b> requires a buffer expansion of the prenesting area, the buffer expansion may be removed after 2 weeks with no breeding activity if the nest is lost to overwash or predation.</p>

Management Activity	Shorebirds		
	Piping Plover	American Oystercatcher and Wilson's Plover	Colonial Waterbirds, including Least Terns, Common Terns, Gull-Billed Terns, and Black Skimmers
<b>Adult Foraging Surveys and Buffer</b>	Suitable breeding habitat will be surveyed three times per week to monitor for adults with an associated scrape or nest territory foraging outside of an existing closure. If birds are observed foraging outside an existing closure, the site will be surveyed daily. If birds are observed foraging outside of a closure on two consecutive surveys, the buffer will be established or expanded using flexible increments based on observed bird behavior to include the foraging site. These closures are intended to provide foraging opportunities close to breeding sites. The closure will be removed if no foraging is observed for a 2-week period during the breeding season, or when associated breeding activity has concluded.	No additional buffers/closures.	No additional buffers/closures.
<b>Unfledged Chicks Surveys</b>	<p><b>ML1:</b> Brood will be observed once daily.</p> <p><b>ML2:</b> Brood will be observed at least one hour each in a.m. and p.m. daily. Monitor(s) will be present during periods of ORV or pedestrian access.</p> <p><b>All:</b> Observations will end once chicks have fledged. Chicks are considered fledged at 35 days of age or when observed in sustained flight of at least 15 meters.</p>	<p><b>ML1:</b> Brood will be observed every other day.</p> <p><b>ML2:</b> Brood will be observed at least once daily. If the brood cannot be located, at least a one-half hour would be spent in efforts to locate the brood/chick.</p> <p><b>All:</b> Observations will end once the chicks have fledged. American oystercatcher chicks are considered fledged if they have been observed to be proficient in flying or observed in sustained flight of at least 30 meters. Wilson's plover chicks are considered fledged if they are observed in sustained flight of at least 15 meters.</p>	<p><b>ML1:</b> Colony will be observed every other day.</p> <p><b>ML2:</b> Colony will be observed daily.</p> <p><b>All:</b> Colonies will be surveyed during the peak hatching period, which should fall 21 days after initial nest observations.</p> <p>A follow-up survey (perimeter count) should be conducted during the peak fledge, which should fall 20 days after hatch counts.</p> <p>Observations will end after no unfledged chicks have been observed on three consecutive surveys.</p>
<b>Unfledged Chick Buffers</b>	<p><b>ML1:</b> A minimum 1,000-meter buffer will be established on either side of the nest when unfledged chicks are present.</p> <p><b>ML2:</b> A 1,000-meter ORV buffer and, where disturbance can be minimized, a 300-meter pedestrian buffer will be established on either side of the nest when unfledged chicks are present. Buffers move with chicks.</p> <p><b>All:</b> The buffer should extend 1,000 meters for ORVs (or 300 meters for pedestrians under ML2) on each side of a line drawn through the nest site and perpendicular to the long axis of the beach. The resulting area (2,000 meters wide for ORVs or 600 meters wide for pedestrians) of protected habitat for piping plover chicks would extend from the oceanside low water line to the soundside low water line or to the farthest extent of dune habitat if no soundside intertidal habitat exists.</p>	<p><b>ML1:</b> A 300-meter buffer will be established around the nest when unfledged chicks are present. If chicks move outside of the buffer, it will be adjusted to include an additional 200 meters from the chicks' location. Closures will be removed 2 weeks after fledging.</p> <p><b>ML2:</b> A 200-meter buffer will be established around the unfledged chicks' location. Foraging and roosting habitat will be included from the ocean (low water line) to the dune (or sound shoreline, if accessible). Buffers will be adjusted/increased as needed when chicks are mobile. Buffers move with chicks.</p> <p>Buffers will remain until Wilson's plover chicks have fledged or 2 weeks after American oystercatcher chicks have fledged (observed flight of 30 meters); a pedestrian corridor may be established prior to the end of the 2-week waiting period for permitting access to the points and spits.</p>	<p><b>ML1:</b> A 300-meter buffer will be established around nests or colony. If chicks move outside of the buffer, it will be adjusted to provide a standard buffer of 200 meters from the chicks' location.</p> <p><b>ML2:</b> A 200-meter buffer will be established around the chicks' location. Buffers will be adjusted as needed when chicks are mobile.</p>
	<b>All Species:</b> Vehicles and/or pedestrians may be allowed to pass through portions of the buffers or closures that are considered inaccessible to chicks because of steep topography, dense vegetation, or other naturally occurring obstacles. Access corridors outside of the prenesting area will be reopened after chicks fledge (except for American oystercatchers, where the area will remain closed for an additional 2 weeks). Prenesting closures can be removed after Jul 31, or 2 weeks after all breeding activity has ceased or chicks have fledged, whichever is later. Areas outside of SMAs would be managed under ML1 measures.		
<b>Breeding Data Collection/Reporting</b>	<p>The following data will be recorded:</p> <p>Date, time, location of breeding pair, courtship behavior, foraging, scrape, nest, or brood observations; identity of observer.</p> <p>Pair, nest, and brood identification number.</p> <p>Number, location, and status of territorial pairs, nesting pairs, nests, eggs, and chicks. GPS will be used to document nest location.</p> <p>Status of eggs/nest and presence/behavior of adults (laying, incubating, lost, abandoned, hatching, hatched).</p> <p>Status of chicks (age, behavior, fledge status) and presence/behavior of adults.</p> <p>Indications of potential predators, humans, pets, or ORVs within posted areas.</p> <p>Indications of cause of nest or chick loss, if apparent.</p> <p>Reproductive rate (chicks fledged per breeding pair).</p>	<p>The following data will be recorded:</p> <p>Date, time, and location of breeding pair, scrape, nest, or brood observations; identity of observer.</p> <p>Pair number; color band (if applicable).</p> <p>Number, location, and status of pairs, scrapes, nests, eggs, and chicks. Use GPS to document nest location.</p> <p>Status of eggs/nest and presence/behavior of adults (laying, incubating, lost, abandoned, hatching, hatched).</p> <p>Status of chicks (age, behavior, fledge status) and presence/behavior of adults.</p> <p>Indications of potential predators, humans, pets, or ORVs within posted areas.</p> <p>Indications of cause of nest or chick loss, if apparent.</p> <p>Reproductive rate (chicks fledged per breeding pair).</p>	<p>The following data will be recorded:</p> <p>Date, time, location, and species of nest/colony observations; identity of observer.</p> <p>Number and location of birds, nests, chicks, and fledglings. GPS will be used to document colony location.</p> <p>Status of colony and presence/behavior of adults (laying, incubating, lost, abandoned).</p> <p>Status of chicks (behavior, fledge status) and presence/behavior of adults.</p> <p>Indications of potential predators, humans, pets, or ORVs within posted areas.</p> <p>Indications of cause of nest or chick loss, if apparent.</p>

Management Activity	Shorebirds		
	Piping Plover	American Oystercatcher and Wilson's Plover	Colonial Waterbirds, including Least Terns, Common Terns, Gull-Billed Terns, and Black Skimmers
<b>Nonbreeding Survey</b>	The NPS will monitor presence, abundance, and behavior of migrating and wintering shorebirds from July through May using the SECN protocol. Survey sites will include all Nonbreeding Shorebird SMAs. The NPS will obtain data similar to International Shorebird Survey data. The following information will be recorded: Date, time, and location of observations; identity of observer; species and number of birds observed; band combination of any banded birds; weather variables and tidal stage; habitat; behavior of the majority of birds in the flock (foraging, resting, disturbed [source will be recorded], other); site management in effect where birds are seen; and number of pedestrians, pets, ORVs and other potential disturbances. Species to be surveyed include piping plover, American oystercatcher, Wilson's plover, red knot, and representative species of colonial waterbirds.		
<b>Nonbreeding Shorebird SMAs</b>	<p><b>All Species:</b> Nonbreeding Shorebird SMAs will be established and managed to reduce disturbance of migrating/wintering shorebirds at various locations throughout the Seashore. Such closures will be installed no later than when breeding season closures are removed at the same location(s). Pets will be prohibited within Nonbreeding Shorebird SMAs.</p> <p><b>Points and Spits:</b> An annual habitat assessment will be conducted after all birds have fledged from the area. Nonbreeding resource closures will be established at the points and spits based on habitat used by wintering piping plovers in more than one (i.e., two or more) of the past 5 years, the presence of birds at the beginning of the migratory season, and suitable habitat types based on the results of the annual survey. This may include VFAs as well as areas closed to all recreational use. Actual locations of suitable foraging and roosting habitat may change periodically due to natural processes. Access to the inlet shorelines, where permitted, will be maintained by a corridor to be determined by NPS staff based on the annual habitat assessment.</p> <p><b>Ocean Shoreline Areas:</b> In addition to the nonbreeding resource closures at the points and spits described above, the NPS will establish VFAs along the ocean shoreline that will provide relatively less-disturbed foraging, resting, and roosting areas for migrating and wintering shorebirds. These may include wider sections of beach with an upper-beach ORV corridor that has a buffer of at least 50 meters above the high tide line, and/or sections of beach that have been designated as vehicle free for other reasons, such as to provide pedestrians with opportunities for a natural beach experience. The following activities are generally compatible with migrating/wintering shorebird use of these areas: pedestrian access for fishing, beach walking, bird-watching, kayaking, kiteboarding, paddleboarding, photography, picnicking, sailing, shelling, stargazing, sunbathing, surfing, swimming, wildlife viewing, windsurfing, and commercial fishing due to the relatively low number and frequency of occurrences. If resource protection staff determines that any single activity or collection of activities is negatively impacting shorebird use of a specific location, the NPS may implement additional restrictions on compatible activities. The location(s) of all ocean shoreline Nonbreeding Shorebird SMAs will be subject to periodic review.</p>		
<b>Adaptive Management Initiatives</b>	<p>The NPS would take an adaptive management approach to the species management program in order to evaluate the effectiveness of and improve the measures identified above. During the course of this plan, the NPS would seek funding and assistance to develop the following adaptive management initiatives related to shorebirds or shorebird habitat:</p> <p><b>Vegetation management:</b> As a pilot project, an adaptive management study to evaluate methods for managing vegetation and improving habitat and wildlife access to available habitat in the Cape Point dredge pond area. The applicability and potential effectiveness of such measures at other locations will be determined.</p> <p><b>Habitat management:</b> As a pilot project, an adaptive management study to evaluate methods of improving shorebird nesting and/or foraging habitat at one location in the Seashore by applying dredge material or by moving/manipulating sand or water at the site. The applicability and potential effectiveness of such measures at other locations will be determined.</p> <p><b>Enhanced predator management:</b> An adaptive management study to evaluate whether predator management actions to be implemented under the (proposed) predator control program for protected species management are effective as is, or whether enhanced measures (such as managing avian predators or ghost crabs) would be beneficial and effective, or are necessary to achieve the desired future conditions for species protection.</p> <p><b>Colonial waterbird social attraction:</b> As a pilot project, an adaptive management study to evaluate the effectiveness of using colonial waterbird decoys and audio-attraction to establish or re-establish colonial waterbird colonies in suitable habitat.</p> <p><b>Piping plover chick fledge rate:</b> An adaptive management study to evaluate the short-term performance target of 1.0 chick fledged per breeding pair, as well as the 1.5 chicks fledged per pair productivity rate identified in the recovery plan, to determine what productivity rate is realistically attainable and would provide for a growing population at the Seashore over the long term. If the actual productivity rate is not sufficient to achieve the desired future conditions for piping plover, it will be determined what management actions (e.g., frequency of monitoring; size or timing of buffers) need to be changed in order to achieve the desired results. The NPS would seek funding for this study as a conservation measure to contribute to the piping plover knowledge base pursuant to its <i>Endangered Species Act</i> recovery responsibilities.</p> <p>After desired future conditions are attained, the NPS would seek funding to develop the following adaptive management initiatives related to resource protection buffers for shorebirds:</p> <p><b>Piping plover chick buffer distance:</b> An adaptive management study to evaluate whether a reduced ORV or pedestrian buffer distance (i.e., less than that stated in this plan) after a certain time period, such as 2 weeks after chicks have hatched, would be adequate to prevent disturbance of piping plover chicks by ORVs and/or pedestrians using adjacent areas during daylight hours.</p> <p><b>Pass-through buffers during the incubation period:</b> An adaptive management study or studies to evaluate whether a reduced buffer distance is adequate to prevent disturbance caused by ORVs driving past piping plover, American oystercatcher, or colonial waterbird nest sites if all other recreation (e.g., pedestrians, pets) is prohibited within the reduced buffer, and to determine whether a reduced buffer is adequate to prevent disturbance caused by pedestrians walking below the high tide line past piping plover, American oystercatcher, or colonial waterbird nest sites.</p>		
<b>Research</b>	In addition to the species management procedures outlined in this table, through the issuance of a research permit, the NPS may authorize qualified researchers associated with recognized academic or research institutions to conduct additional scientific research on the respective species that will add to the existing knowledge of shorebird species or improve resource protection within the Seashore. Establishment of Research Areas may be authorized under such a permit.		
<b>Implementation of Adaptive Management and Research Initiatives</b>	Should adaptive management initiatives and other research provide information that the NPS believes is an adequate basis for management changes, such changes would be evaluated and considered for implementation as part of the 5-year periodic review process described at the end of this table.		

Management Activity	Sea Turtles
<b>Survey Time and Frequency</b>	<p>Sea turtle patrol will begin on May 1, unless leatherback nests have been reported within the state, in which case, the Seashore will follow the direction of NCWRC. Patrol will continue until Sep 15, or 2 weeks after the last sea turtle nest or crawl is found, whichever is later.</p> <p>Daily surveys will be conducted by ATV/UTV and possibly ORV for crawls and nests on all beaches, generally in the morning before onset of public ORV use. Daily surveys for nests end Sep 15, or 2 weeks after the last sea turtle nest or crawl is found, whichever is later. Periodic monitoring (e.g., every 2 to 3 days) for unknown nesting and emerging hatchlings will continue, especially in areas of high visitation, from that date until Nov 15.</p> <p>Monitoring will also occur for post-hatchling washbacks during periods when there are large quantities of seaweed washed ashore or following severe storm events. Nest observations will stop when all nests have hatched or excavation indicates that unhatched nests are not viable.</p> <p>Once a light filter fence is installed, nests will be monitored daily for signs of hatchling emergence.</p>
<b>Sea Turtle Data Collection/Reporting</b>	<p>At a minimum, the NCWRC handbook will be followed and the following will be recorded:</p> <ul style="list-style-type: none"> <li>• Date, location, and species of nests and false crawls; identity of observer.</li> <li>• Whether nests need to be relocated and, if so, why and where (new physical description and GPS location), number of eggs relocated, and time of day.</li> <li>• Necessary protective measures for nests and hatchlings.</li> <li>• Information regarding any post-hatching nest excavation and analysis.</li> </ul> <p>All nests will be examined after hatching to determine productivity rates. Nests will be excavated in the evening, a minimum of 72 hours after the hatching event. In cases where hatching events or dates are unknown, nest cavities will be unearthed 80–90 days after the lay date. Any live hatchlings found during excavations will be released at dusk or after dark on the same day as excavation.</p> <p>For strandings, the following will be recorded: species, location (GPS), measurements, indications of human interactions, and disposition of animal/carcass. Samples and photos will be collected when necessary. Necropsies will be conducted when possible.</p>
<b>Nest Closures/Buffers</b>	<p>A buffer approximately 10 × 10 meters will be established with symbolic fencing and signage around nest. Closure size may be modified depending on environmental conditions at the nest site.</p> <p>Approximately 50–55 days into incubation, closures will be expanded to the surf line. The width of the closure will be based on the type and level of use in the area of the beach where the nest was laid:</p> <ol style="list-style-type: none"> <li>1. VFAs with little or no pedestrian traffic—25 meters wide (total).</li> <li>2. Village beaches or other areas with high levels of pedestrian and other vehicle free use—50 meters wide (total).</li> <li>3. Areas with ORV traffic—105 meters wide (total).</li> </ol> <p>On the landward side of the nest, the closed area will be expanded to 15 meters from the nest where possible, but no less than 10 meters landward from the nest. If appropriate, traffic detours behind the nest area will be established and clearly marked with signs and reflective arrows.</p> <p>Light-filtering fence will be used in a U-shaped configuration around nests nearing their hatch dates, with the open face of the U oriented toward the water, to block light pollution from the villages and vehicles operating on the beach after dark.</p> <p>Once the buffer expansion is implemented, NPS staff will use rakes or a steel mat attached to an ATV to smooth any vehicle tracks between the nest and the water, so that tracks do not impede hatchlings from reaching the water.</p> <p>If multiple nests are located near each other (within 50 meters), and have similar hatch dates (within 14 days of each other), then closures will encompass all nests in the area and will not be removed until all nests within the closure have hatched.</p>
<b>Nest Watch Program</b>	<p>A cadre of trained volunteers will be established to watch nests that have reached their hatch windows in order to monitor hatchling emergence success and success reaching the water, and to provide for the minimization of negative impacts from artificial lighting, predation, and human disturbance. Depending on the number of nests that may be ready to hatch and the availability of volunteers, it may be necessary for NPS turtle staff to prioritize which nests are watched on any particular night. Priority will be given to watching the nests that are most likely to be negatively impacted by manageable factors.</p>
<b>Nest Relocation</b>	<p>By Apr 15, areas deemed unsuitable for turtle nests (e.g., those with a high erosion rate) will be identified by Seashore staff. Maps and descriptions of these areas will be analyzed by NCWRC prior to nesting season.</p> <p>When a nest is found, designated NPS staff members will assess the need for nest relocation and follow relocation guidance identified in the NCWRC handbook.</p> <p>If it is determined that the nest will not be relocated, it will be immediately protected with symbolic fencing and signs approximately 10 × 10 meters in size. Closure size may vary at the discretion of NPS staff depending on the environmental factors at a nest location.</p> <p>If a nest is threatened by an imminent storm event, NPS will consult with NCWRC to determine appropriate action.</p>
<b>Strandings</b>	<p>The Seashore will respond to sea turtle strandings in a timely manner, and will forward or report all information, pictures, and signs of human interaction to NCWRC.</p> <p>Necropsies of stranded turtles will be done when possible.</p>
<b>Light Restrictions</b>	<p>From May 1 through Nov 15:</p> <ul style="list-style-type: none"> <li>• Portable lanterns, auxiliary lights, and powered fixed lights of any kind shining for more than 5 minutes at a time would be prohibited on Seashore ocean beaches.</li> <li>• Beach fires would be allowed/restricted as described in the respective alternatives.</li> </ul>
<b>Night-Driving Restrictions</b>	<p>From May 1 to Nov 15, all non-essential vehicle use is restricted or prohibited as described in the respective alternatives.</p>
<b>Light Management</b>	<p>By May 1, 2012, turtle-friendly lighting fixtures will be installed on all Seashore structures visible from the ocean beach (except where prevented by other overriding lighting requirements, such as lighthouses, which serve as aids to navigation) and fishing piers operated by NPS concessioners.</p> <p>Educational material will be developed to inform visitors about their impact on the success of sea turtle nests.</p> <p>The Seashore will work with the USFWS, the NCWRC, and Dare County to encourage development of a turtle-friendly lighting education program for villages within the Seashore on Hatteras Island.</p>

Management Activity	Sea Turtles
<b>Adaptive Management Initiatives</b>	<p>The NPS would take an adaptive management approach to the species management program in order to evaluate the effectiveness of and improve the measures identified above. During the course of this plan, the NPS would seek funding and assistance to develop the following adaptive management initiatives for sea turtles:</p> <ul style="list-style-type: none"> <li>• An assessment tool to measure ambient artificial lighting along the length of the Seashore, which can be used to reassess conditions after any management actions (such as a lighting ordinance) are implemented to reduce artificial lighting. After light management actions are implemented, levels of lighting will be reassessed and impacts on sea turtle nesting success will be monitored and evaluated. If supported by the findings, the NPS will work toward an incremental adjustment (i.e., increase) in nighttime ORV access to limited select locations where not in substantial conflict with turtle nesting and hatchling activity.</li> <li>• An adaptive management study to evaluate the level of human disturbance, if any, that might be caused by designating night-driving routes to select points and spits, and to develop management tools to minimize impacts to an acceptable level. If supported by the findings, the NPS will work toward an incremental adjustment (i.e., increase) in nighttime ORV access to limited select locations where not in substantial conflict with turtle nesting and hatchling activity.</li> <li>• An adaptive management study to determine ways to increase the number of hatchlings that emerge and reach the water. The NPS would seek funding for this study as a conservation measure to contribute to the sea turtle knowledge base pursuant to its <i>Endangered Species Act</i> recovery responsibilities.</li> </ul>
<b>Research</b>	In addition to the species management procedures outlined in this table, through the issuance of a research permit, the NPS may authorize qualified researchers associated with recognized academic or research institutions to conduct additional scientific research on turtle species that will add to the existing knowledge of sea turtles or improve resource protection within the Seashore. Establishment of research areas could be authorized under such a permit.
<b>Implementation of Adaptive Management and Research Initiatives</b>	Should adaptive management initiatives and other research provide information that NPS believes is an adequate basis for management changes, such changes would be evaluated and considered for implementation as part of the 5-year periodic review process.
Management Activity	Seabeach Amaranth
<b>Survey Time and Frequency</b>	<p>Jul to Sep: Before removing any shorebird closures, surveys will be conducted for seabeach amaranth seedlings/plants.</p> <p>Aug: A Seashore-wide annual survey for seabeach amaranth will be conducted in all potential habitats. Some shorebird closures may not be surveyed until just prior to reopening an area to ORV traffic to minimize disturbance of nesting birds or chicks.</p> <p>Observations will end when all known seabeach amaranth plants have died back.</p>
<b>Data Collection</b>	The location of all individual plants or plant clusters will be recorded using GPS. It will be noted whether the plant is located in an area open or closed to recreational use.
<b>Buffers/Closures</b>	<p>Prior to Jun 1, suitable seabeach amaranth habitat will be identified at points and spits where plants have observed within the last 5 years and delineated with symbolic fencing if such areas are not already protected within existing shorebird resource closures.</p> <p>If a plant/seedling is found outside of an existing closure, symbolic fencing with signage will be erected creating a 10- x 10-meter buffer around the plant. If plants are located next to one another, the area will be expanded to create one enclosure protecting several plants.</p> <p>If a seabeach amaranth plant is found during the survey prior to reopening a bird closure to ORV and pedestrian use, the Seashore will protect the plant as described above and reopen the portions of the bird closure where seabeach amaranth plants do not exist.</p> <p>If seabeach amaranth is not present by Sep 1, seabeach amaranth buffers will be removed. If seabeach amaranth is present, buffers will remain until after the plants have senesced, which is typically around Dec 1.</p>
<b>Adaptive Management Initiatives</b>	<p>NPS would take an adaptive management approach to the species management program in order to evaluate the effectiveness of and improve the measures identified above. During the course of this plan, NPS would seek funding and assistance to develop the following adaptive management initiatives for seabeach amaranth:</p> <ul style="list-style-type: none"> <li>• A study to assess the feasibility of seabeach amaranth restoration at up to four suitable sites. NPS would seek funding for this study as a conservation measure to contribute to the seabeach amaranth knowledge base pursuant to its <i>Endangered Species Act</i> recovery responsibilities.</li> </ul>
Management Activity	All Species
<b>Periodic Review</b>	A systematic review of data, annual reports, and other information would be conducted by NPS every 5 years, after storms or events that Seashore management determines to be a major modification of habitat quantity or quality, or if necessitated by a significant change in protected species status (e.g., listing or de-listing), in order to evaluate the effectiveness of management actions in making progress toward the accomplishment of stated objectives. Periodic review could result in changes to the management actions in order to improve effectiveness. When desired future conditions for resources are met or exceeded, periodic review and adaptive management may allow for more flexible management of recreational use, provided adverse impacts of such use are effectively managed and wildlife populations remained stable. Where progress is not being made toward the attainment of desired future conditions, periodic review and adaptive management may provide for additional management including appropriate restrictions on recreational use.

**TABLE 10-1. SPECIES MANAGEMENT STRATEGIES FOR ALTERNATIVE F**

DEFINITIONS			
<p><b>Breeding behavior:</b> Shorebird behavior that includes, but is not limited to, courtship, mating, scraping, confirmed scrapes, and other breeding or nest-building activities. The terms breeding behavior and breeding activity are used synonymously.</p> <p><b>Human disturbance:</b> Any human activity that changes the contemporaneous behavior of beach nesting birds that are breeding, nesting, foraging, or roosting, or migrating/wintering birds that are using the beach and associated habitats for foraging, resting, or roosting. Bird behaviors indicating disturbance include defensive displays; alarm calls; flushing or leaving a nest or feeding area; and diving or mobbing pedestrians, dogs, or vehicles.</p> <p><b>Periodic review:</b> A systematic review of data, habitat conditions, and other information to be conducted by the NPS every 5 years, or after storms or events that Seashore management determines to be a major modification of habitat quantity or quality, or after a significant change in protected species status (e.g., listing or de-listing), in order to evaluate the effectiveness of management actions in making progress toward the accomplishment of stated objectives. Periodic review could result in changes to the management actions in order to improve effectiveness. When desired future conditions for resources are met or exceeded,</p>		<p>periodic review and adaptive management may allow for more flexible management of recreational use, provided adverse impacts of such use are effectively managed and wildlife populations remained stable. Where progress is not being made toward goals, periodic review and adaptive management may result in <u>increased</u> restrictions on recreational use.</p> <p><b>Prenesting closure:</b> A kind of resource closure in which an area of suitable habitat is proactively closed at the start of the shorebird breeding season to provide undisturbed habitat for bird breeding activities to occur.</p> <p><b>Research area:</b> Area of suitable habitat set aside on a temporary or long-term basis (such as a study site or control plot) as part of a research project authorized by NPS under a research permit.</p> <p><b>Resource closure:</b> Any area posted as closed to all public entry in order to protect wildlife, such as breeding and foraging shorebirds and bird and turtle nests, or vegetation from human disturbance.</p>	
Management Activity	Shorebirds		
	Piping Plover and Wilson's Plover	American Oystercatcher	Colonial Waterbirds, including Least Terns, Common Terns, Gull-Billed Terns, and Black Skimmers
Prenesting Surveys	Mar 15 to Jul 15: Prenesting closures will be surveyed three times per week. Outside of prenesting closures, suitable habitat will be surveyed twice per week, increasing to three times per week once birds are present.	Mar 15 to Jul 15: Prenesting closures will be surveyed three times per week. Outside of prenesting closures, suitable habitat will be surveyed twice per week, increasing to three times per week once breeding pairs are present.	May 1 to Jul 15: Prenesting closures will be surveyed three times per week. Outside of prenesting closures, suitable habitat will be surveyed twice per week, increasing to three times per week once breeding pairs are present.
Prenesting Closures	<p><b>All species:</b> By <b>Mar 1</b>, Seashore staff will evaluate all potential breeding habitat for piping plover, Wilson's plover and American oystercatcher and recommend prenesting closures for those species based on that evaluation. CWB breeding habitat will be evaluated by <b>Apr 1</b>. Areas of newly created habitat will also be evaluated during the annual habitat assessment Areas of suitable habitat that have had individual PIPL, WIPL or AMOY nests, or concentrations of more than 10 CWB nests in more than one of the past five years and new habitat that is particularly suitable for shorebird nesting, such as the habitat at new inlets or overwash areas, will be posted as prenesting closures using symbolic fencing (string between posts) or with other closure signs by <b>Mar 15</b> at sites involving piping plover, Wilson's plover, and/or American oystercatcher; and by <b>Apr 15</b> at sites involving only colonial waterbirds. Because CWB colonies may shift locations from year to year, ORV ramps and pedestrian access points that have had colonies in more than one of the past five years will remain open until scraping or nesting is observed. Prenesting closures adjacent to such ramps and access points will still be established in these areas, subject to standard buffers once scraping or nesting is observed. The NPS will determine the configuration of specific prenesting closures based on an annual habitat assessment. Once established at the beginning of the breeding season, these areas would not be reduced to accommodate an ORV corridor. Prenesting closures would be removed if no breeding activity is seen in the area by <b>Jul 31</b> (or <b>Aug 15</b> if black skimmers are present), or 2 weeks after all chicks have fledged, whichever comes later. Nonbreeding shorebird habitat protection would be implemented, as described later in this table, before prenesting areas are removed. Pedestrian access along ocean and inlet shorelines below the high tide line will be permitted in front of (i.e., seaward of) prenesting areas until breeding activity is observed, then standard buffers for breeding activity would apply. <b>The NPS retains discretion at all times to enforce more protective closures or take other measures, if considered necessary, consistent with its obligations under the law.</b></p> <p>Pets and horses are prohibited in pedestrian shoreline access areas in front of prenesting areas. ORVs, pedestrians, pets and horses are prohibited within all resource closures, including prenesting closures.</p> <p><b>ORV corridors at Cape Point and South Point:</b> When prenesting closures are implemented, the ORV access corridor at Cape Point and South Point will be reduced from 50 meters (164 feet) during the nonbreeding season to 35 meters (115 feet). Once established, the prenesting closure will not be modified if the beach erodes into the ORV corridor or into the protected habitat. Once breeding activity is observed, standard buffers for breeding activity will apply. The ORV corridor width will be restored to 50 meters (164 feet) after breeding activity is completed at the site and prenesting closures are removed.</p>		
Courtship/Mating Surveys	<b>All species:</b> Prenesting closures would be surveyed three times per week. Outside of prenesting closures, potential suitable habitat would be surveyed three times per week once breeding pairs are present.		
Courtship/Mating Buffers	<b>All species:</b> The Seashore retains the discretion to expand courtship/mating buffers depending on bird behavior. In unprotected areas, a buffer will be established within 12 daylight hours when courtship or mating by piping plover, Wilson's plover or American oystercatchers is observed. When courtship or mating is observed in the immediate vicinity of paved roads, parking lots, campgrounds, buildings, and other facilities, such as within the villages or at NPS developed sites, NPS retains the discretion to provide resource protection to the extent possible while still allowing those facilities to remain operational. This provision does not apply to ORV routes or ORV ramp access, which would be subject to standard buffers.		
	<p>If breeding activity is observed outside of an existing closure or within a closure less than the prescribed buffer distance from the closure boundary, a buffer will be established or expanded to ensure a 75-meter buffer for the observed birds.</p> <p>Buffers will be increased in 50-meter increments if human disturbance* occurs.</p> <p>Outside of prenesting areas, closures will be removed if no breeding activity is observed for a 2-week period, or when associated breeding activity has concluded.</p> <p>*Buffers are not expanded for incidental disturbance associated with required NPS protected species monitoring.</p>	<p>If breeding activity is observed outside of an existing closure or within a closure less than the prescribed buffer distance from the closure boundary, a buffer will be established or expanded to ensure a 150-meter buffer for the observed birds.</p> <p>Buffers will be increased in 50-meter increments if human disturbance occurs.</p> <p>Outside of prenesting areas, closures will be removed if no breeding activity is observed for at least a 2-week period, or when associated breeding activity has concluded.</p>	<p>Buffer establishment will be based on the location of scrape(s) and not location of copulation or "fish flashing."</p>

Management Activity	Shorebirds		
	Piping Plover and Wilson's Plover	American Oystercatcher	Colonial Waterbirds, including Least Terns, Common Terns, Gull-Billed Terns, and Black Skimmers
<b>Scrape/Nest Surveys</b>	<p>A walk-through will be conducted to look for scrapes/nests every 3 days until such monitoring will disrupt other nesting species in the area. Monitoring of known and potential breeding areas will continue from a distance.</p> <p>Nests will be observed daily from a distance that does not disturb the birds, based on professional judgment.</p> <p>Nests will be approached once per week to observe and record data.</p>	<p>A walk-through will be conducted to look for scrapes/nests when observations suggest a scrape or nest is present.</p> <p>Nests will be observed daily from a distance that does not disturb the birds, based on professional judgment.</p> <p>For incubating birds that cannot be observed from a distance, nests will be checked every 3 days.</p>	<p>If scrape(s)/nest(s) are observed outside a resource closure or within a closure less than the prescribed buffer distance from the closure boundary, a 100-meter buffer will be established around the scrape location for least terns (if only least terns are present), or a 200-meter buffer when other colonial waterbird species are present. Buffers will be increased in 50-meter increments if human disturbance occurs.</p> <p>Colonies will be surveyed during the peak nesting period for each species, which generally is during the first part of June for tern species, but could be later for species such as black skimmers.</p> <p>Nests will be observed daily from a distance that does not disturb the birds, based on professional judgment.</p> <p>For incubating birds that cannot be observed from a distance, colony activity will be checked every 3 days.</p>
<b>Scrape/Nest Buffers</b>	<p><b>All species:</b> The Seashore retains the discretion to expand scrape or nest buffers as needed to protect resources. In unprotected areas, a buffer will be established immediately when a nest with egg(s) is found. Prior to hatching, vehicles may pass by such areas within designated ORV access corridors that have been established along the outside edge of nesting habitat where, in the judgment of Seashore resources management staff, steep topography, dense vegetation, or other naturally-occurring obstacles minimize the risk of human disturbance. Such sites will be re-evaluated for disturbance during each subsequent survey. When scrape(s), nest(s) or chick(s) occur in the immediate vicinity of paved roads, parking lots, campgrounds, buildings, and other facilities, such as within the villages or at NPS developed sites, the NPS retains the discretion to provide resource protection to the extent possible while still allowing those facilities to remain operational. Regardless of the nature of the adjacent facilities, in all cases, as a minimum, NPS would provide signs, fencing and reduced buffers to protect nest(s) and chick(s) once they occur. This provision does not apply to ORV routes or ORV ramp access, which would be subject to standard buffers. Buffers will remain in place for 2 weeks after a nest is lost to determine if the pair will re-nest. For buffers that occur outside of, or that expand, the original prenesting areas, the buffer or expansion will be removed if no breeding activity is observed for a 2-week period, or when associated breeding activity has concluded.</p>		
	<p>A 75-meter buffer/closure will be established around scrape(s) or nest(s). Buffers will be increased in 50-meter increments if human disturbance occurs.</p> <p>If a buffer falls within the intertidal zone, a full-beach closure will result.</p>	<p>A 150-meter buffer/closure will be established around scrape(s) or nest(s). Buffers will be increased in 50-meter increments if human disturbance occurs.</p> <p>If a buffer falls within the intertidal zone, a full-beach closure will result.</p>	<p>A 100-meter buffer/closure will be established around a least tern scrape, nest or colony.</p> <p>A 200-meter buffer/closure will be established around the scrape, nest or colony if any common terns, gull-billed terns, or black skimmers are present.</p> <p>Buffers will be increased in 50-meter increments if human disturbance occurs.</p> <p>If a buffer falls within the intertidal zone, a full-beach closure will result.</p>
<b>Adult Foraging Surveys and Buffer</b>	<p><b>PIPL:</b> Suitable breeding habitat will be surveyed three times per week to monitor for adults with an associated scrape or nest territory foraging outside of an existing closure. If birds are observed foraging outside an existing closure, the site will be surveyed daily. If birds are observed foraging outside of a closure on two consecutive surveys, the buffer will be established or expanded using flexible increments based on observed bird behavior to include the foraging site. These closures are intended to provide foraging opportunities close to breeding sites. The closure will be removed if no foraging is observed for a 2-week period during the breeding season, or when associated breeding activity has concluded.</p> <p><b>WIPL:</b> No additional buffers/closures.</p>	<p>No additional buffers/closures.</p>	<p>No additional buffers/closures.</p>
<b>Unfledged Chick Surveys</b>	<p><b>PIPL:</b> Brood will be observed at least one hour each in a.m. and p.m. daily.</p> <p><b>WIPL:</b> Observe brood once daily.</p> <p><b>All:</b> Observations will end once chicks have fledged. Chicks are considered fledged at 35 days of age or when observed in sustained flight of at least 15 meters.</p>	<p>Brood will be observed at least once daily. If the brood cannot be located, at least one-half hour will be spent in efforts to locate the brood/chick.</p> <p>Observations will end once the chicks have fledged. Chicks are considered fledged if they have been observed to be proficient in flying or observed in sustained flight of at least 30 meters.</p>	<p>Colony will be observed daily.</p> <p>Observations will end after no unfledged chicks have been observed on three consecutive surveys. Chicks are considered fledged if they have been observed to be proficient in flying or observed in sustained flight of at least 15 meters.</p>

Management Activity	Shorebirds		
	Piping Plover and Wilson's Plover	American Oystercatcher	Colonial Waterbirds, including Least Terns, Common Terns, Gull-Billed Terns, and Black Skimmers
<b>Unfledged Chick Buffers</b>	<p><b>PIPL:</b> A 1,000-meter ORV buffer and, where disturbance can be minimized, a 300-meter pedestrian buffer will be established on either side of the nest when unfledged chicks are present. Buffers move with chicks.</p> <p>The buffer should extend 1,000 meters for ORVs (or 300 meters for pedestrians) on each side of a line drawn through the nest site and perpendicular to the long axis of the beach. The resulting area (2,000 meters wide for ORVs or 600 meters wide for pedestrians) of protected habitat for piping plover chicks would extend from the oceanside low water line to the soundside low water line or to the farthest extent of dune habitat if no soundside intertidal habitat exists.</p> <p><b>WIPL:</b> A 200-meter buffer will be established around the unfledged chicks' location. Foraging and roosting habitat will be included from the ocean (low water line) to the dune (or sound shoreline, if accessible). Buffers will be adjusted/increased as needed when chicks are mobile. Buffers move with chicks.</p>	<p>A 200-meter buffer will be established around the unfledged chicks' location. Foraging and roosting habitat will be included from the ocean (low water line) to the dune (or sound shoreline, if accessible). Buffers will be adjusted/increased as needed when chicks are mobile. Buffers move with chicks.</p> <p>In areas designated for ORV use, buffers will remain until 2 weeks after American oystercatcher chicks have fledged (observed flight of 30 meters); a pedestrian corridor may be established prior to the end of the 2-week waiting period for permitting access to the points and spits.</p>	<p>A 200-meter buffer will be established around the chicks' location. Buffers will be adjusted as needed when chicks are mobile.</p>
	<p><b>All Species:</b> Vehicles and/or pedestrians may be allowed to pass through portions of the buffers or closures that are considered inaccessible to chicks because of steep topography, dense vegetation, or other naturally occurring obstacles. Access corridors outside of the prenesting area will be reopened after chicks fledge (except for American oystercatchers, where the area will remain closed for an additional 2 weeks). Prenesting closures can be removed after Jul 31, or 2 weeks after all breeding activity has ceased or chicks have fledged, whichever is later.</p>		
<b>Breeding Data Collection/Reporting</b>	<p>The following data will be recorded:</p> <ul style="list-style-type: none"> <li>• Date, time, location of breeding pair, courtship behavior, foraging, scrape, nest, or brood observations; identity of observer.</li> <li>• Pair, nest, and brood identification number.</li> <li>• Number, location, and status of territorial pairs, nesting pairs, nests, eggs, and chicks. GPS will be used to document nest location.</li> <li>• Status of eggs/nest and presence/behavior of adults (laying, incubating, lost, abandoned, hatching, hatched).</li> <li>• Status of chicks (age, behavior, fledge status) and presence/behavior of adults.</li> <li>• Indications of potential predators, humans, pets, or ORVs within posted areas.</li> <li>• Indications of cause of nest or chick loss, if apparent.</li> <li>• Reproductive rate (chicks fledged per breeding pair).</li> </ul>	<p>The following data will be recorded:</p> <ul style="list-style-type: none"> <li>• Date, time, and location of breeding pair, scrape, nest, or brood observations; identity of observer.</li> <li>• Pair number; color band (if applicable).</li> <li>• Number, location, and status of pairs, scrapes, nests, eggs, and chicks. Use GPS to document nest location.</li> <li>• Status of eggs/nest and presence/behavior of adults (laying, incubating, lost, abandoned, hatching, hatched).</li> <li>• Status of chicks (age, behavior, fledge status) and presence/behavior of adults.</li> <li>• Indications of potential predators, humans, pets, or ORVs within posted areas.</li> <li>• Indications of cause of nest or chick loss, if apparent.</li> <li>• Reproductive rate (chicks fledged per breeding pair).</li> </ul>	<p>The following data will be recorded:</p> <ul style="list-style-type: none"> <li>• Date, time, location, and species of nest/colony observations; identity of observer.</li> <li>• Number and location of birds, nests, chicks, and fledglings. GPS will be used to document colony location.</li> <li>• Status of colony and presence/behavior of adults (laying, incubating, lost, abandoned).</li> <li>• Status of chicks (behavior, fledge status) and presence/behavior of adults.</li> <li>• Indications of potential predators, humans, pets, or ORVs within posted areas.</li> <li>• Indications of cause of nest or chick loss, if apparent.</li> </ul>
<b>Nonbreeding Survey</b>	<p>The NPS will monitor and document the presence, abundance, and behavior of migrating and wintering shorebirds from July through May. The NPS will obtain data similar to International Shorebird Survey data. The following information will be recorded: Date, time, and location of observations; identity of observer; species and number of birds observed; weather variables and tidal stage; habitat; behavior of the majority of birds in the flock (foraging, resting, disturbed [source will be recorded], other); site management in effect where birds are seen; and number of pedestrians, pets, ORVs and other potential disturbances. Species to be surveyed include piping plover, American oystercatcher, Wilson's plover, red knot, and other selected species. Species recently added to the surveys include whimbrel, sanderling, and black-necked stilt.</p>		
<b>Nonbreeding Shorebird Habitat Protection</b>	<p><b>All Species:</b> VFAs throughout the Seashore will provide relatively less disturbed foraging, resting, and roosting habitat for migrating and wintering birds. These areas will be open to pedestrians for recreational use. Pets on a leash in accordance with existing regulations will be permitted in VFAs, except as previously noted for pedestrian shoreline access in front of prenesting closures.</p> <p><b>Points and Spits:</b> An annual habitat assessment will be conducted after all birds have fledged from the area. Prior to removing prenesting closures, resource closures will be established in the most sensitive portions of nonbreeding shorebird habitat at the points and spits based on habitat used by wintering piping plovers in more than one (i.e., two or more) of the past 5 years, the presence of birds at the beginning of the migratory season, and suitable habitat types based on the results of the annual habitat assessment. People and pets will be prohibited in these resource closures. Actual locations of suitable foraging and roosting habitat may change periodically due to natural processes. Access to the inlet shorelines, where permitted, will be maintained by a corridor to be determined by NPS staff based on the annual habitat assessment. For the nonbreeding season, the ORV corridor at Bodie Island Spit, Cape Point and South Point will be established at 50 meters (164 feet) after breeding activity is completed and prenesting closures are removed.</p>		

Management Activity	Shorebirds		
	Piping Plover and Wilson's Plover	American Oystercatcher	Colonial Waterbirds, including Least Terns, Common Terns, Gull-Billed Terns, and Black Skimmers
<b>Adaptive Management Initiatives</b>	<p>The NPS would take an adaptive management approach to the species management program in order to evaluate the effectiveness of and improve the measures identified above. During the course of this plan, the NPS would seek funding and assistance to develop the following adaptive management initiatives related to shorebirds or shorebird habitat:</p> <p><b>Vegetation management:</b> As a pilot project, an adaptive management study to evaluate methods for managing vegetation and improving habitat and wildlife access to available habitat in the Cape Point dredge pond area. The applicability and potential effectiveness of such measures at other locations will be determined.</p> <p><b>Habitat management:</b> As a pilot project, an adaptive management study to evaluate methods of improving shorebird nesting and/or foraging habitat at one location in the Seashore by applying dredge material or by moving/manipulating sand or water at the site. The applicability and potential effectiveness of such measures at other locations will be determined.</p> <p><b>Enhanced predator management:</b> An adaptive management study to evaluate whether predator management actions to be implemented under the (proposed) predator control program for protected species management are effective as is, or whether enhanced measures (such as managing avian predators or ghost crabs) would be beneficial and effective, or are necessary to achieve the desired future conditions for species protection.</p> <p><b>Colonial waterbird social attraction:</b> As a pilot project, an adaptive management study to evaluate the effectiveness of using colonial waterbird decoys and audio-attraction to establish or re-establish colonial waterbird colonies in suitable habitat.</p> <p><b>Piping plover chick fledge rate:</b> An adaptive management study to evaluate the short-term performance target of 1.0 chick fledged per breeding pair, as well as the 1.5 chicks fledged per pair productivity rate identified in the recovery plan, to determine what productivity rate is realistically attainable and would provide for a growing population at the Seashore over the long term. If the actual productivity rate is not sufficient to achieve the desired future conditions for piping plover, it will be determined what management actions (e.g., frequency of monitoring; size or timing of buffers) need to be changed in order to achieve the desired results. The NPS would seek funding for this study as a conservation measure to contribute to the piping plover knowledge base pursuant to its <i>Endangered Species Act</i> recovery responsibilities.</p> <p>After desired future conditions are attained, the NPS would seek funding to develop the following adaptive management initiatives related to resource protection buffers for shorebirds:</p> <p><b>Piping plover chick buffer distance:</b> An adaptive management study to evaluate whether a reduced ORV or pedestrian buffer distance (i.e., less than that stated in this plan) after a certain time period, such as 2 weeks after chicks have hatched, would be adequate to prevent disturbance of piping plover chicks by ORVs and/or pedestrians using adjacent areas during daylight hours.</p> <p><b>Pass-through buffers during the incubation period:</b> An adaptive management study or studies to evaluate whether a reduced buffer distance is adequate to prevent disturbance caused by ORVs driving past piping plover, American oystercatcher, or colonial waterbird nest sites if all other recreation (e.g., pedestrians, pets) is prohibited within the reduced buffer, and to determine whether a reduced buffer is adequate to prevent disturbance caused by pedestrians walking below the high tide line past piping plover, American oystercatcher, or colonial waterbird nest sites.</p> <p><b>Nonbreeding shorebird management:</b> Develop an adaptive management study to evaluate nonbreeding shorebird utilization of shoreline habitat that is open to ORV use compared to habitat that is not open to ORV use. Utilize findings in the future to determine best location and configuration of ORV corridors in areas designated for ORV use.</p>		
<b>Research</b>	<p>In addition to the species management procedures outlined in this table, through the issuance of a research permit, the NPS may authorize qualified researchers associated with recognized academic or research institutions to conduct additional scientific research on the respective species that will add to the existing knowledge of shorebird species or improve resource protection within the Seashore. Establishment of Research Areas may be authorized under such a permit.</p>		
<b>Implementation of Adaptive Management and Research Initiatives</b>	<p>Should adaptive management initiatives and other research provide information that the NPS believes is an adequate basis for management changes, such changes would be evaluated and considered for implementation as part of the 5-year periodic review process described at the end of this table.</p>		
Management Activity	Sea Turtles		
<b>Survey Time and Frequency</b>	<p>Sea turtle patrol will begin on May 1, unless leatherback nests have been reported within the state, in which case, the Seashore will follow the direction of NCWRC. Patrol will continue until Sep 15, or 2 weeks after the last sea turtle nest or crawl is found, whichever is later.</p> <p>Daily surveys will be conducted by UTV (and occasionally by ORV) to search for crawls and nests on all oceanside beaches and spits, generally in the morning before onset of public ORV use. Daily surveys for nests end Sep 15, or 2 weeks after the last sea turtle nest or crawl is found, whichever is later. Periodic monitoring (e.g., every 2 to 3 days) for unknown nesting and emerging hatchlings will continue, especially in areas of high visitation, from that date until Nov 15.</p> <p>Monitoring will also occur for post-hatchling washbacks during periods when there are large quantities of seaweed washed ashore or following severe storm events. Nest observations will stop when all nests have hatched or excavation indicates that unhatched nests are not viable.</p> <p>Once a light filter fence is installed, nests will be monitored daily for signs of hatchling emergence.</p>		
<b>Sea Turtle Data Collection/Reporting</b>	<p>At a minimum, the NCWRC handbook will be followed and the following will be recorded:</p> <ul style="list-style-type: none"> <li>• Date, location, and species of nests and false crawls; identity of observer.</li> <li>• Whether nests need to be relocated and, if so, why and where (new physical description and GPS location), number of eggs relocated, and time of day.</li> <li>• Necessary protective measures for nests and hatchlings.</li> <li>• Information regarding any post-hatching nest excavation and analysis.</li> </ul> <p>All nests will be examined after hatching to determine productivity rates. Nests will be excavated in the evening, a minimum of 72 hours after the hatching event. In cases where hatching events or dates are unknown, nest cavities will be unearthed 80–90 days after the lay date. Any live hatchlings found during excavations will be released at dusk or after dark on the same day as excavation.</p> <p>For strandings, the following will be recorded: species, location (GPS), measurements, indications of human interactions, and disposition of animal/carcass. Samples and photos will be collected when necessary. Necropsies will be conducted when possible.</p>		

Management Activity	Sea Turtles
<b>Nest Closures/Buffers</b>	<p>A buffer approximately 10 × 10 meters will be established with symbolic fencing and signage around nest. Closure size may be modified depending on environmental conditions at the nest site. Approximately 50–55 days into incubation, closures will be expanded to the surf line. The width of the closure will be based on the type and level of use in the area of the beach where the nest was laid:</p> <ol style="list-style-type: none"> <li>1. VFAs with little or no pedestrian traffic—25 meters wide (i.e., 12.5 meters on either side of the nest).</li> <li>2. Village beaches or other areas with high levels of pedestrian and other non-ORV use—50 meters wide (i.e., 25 meters on either side of the nest).</li> <li>3. Areas with ORV traffic—105 meters wide (i.e., 52.5 meters on either side of the nest).</li> </ol> <p>On the landward side of the nest, the closed area will be expanded to 15 meters from the nest where possible, but no less than 10 meters landward from the nest. If appropriate, traffic detours behind the nest area will be established and clearly marked with signs and reflective arrows.</p> <p>Light-filtering fence will be used in a U-shaped configuration around nests nearing their hatch dates, with the open face of the U oriented toward the water, to block light pollution from the villages and vehicles operating on the beach after dark.</p> <p>Once the buffer expansion is implemented, NPS staff will use rakes or a steel mat attached to an ATV or UTV to smooth any vehicle tracks between the nest and the water, so that tracks do not impede hatchlings from reaching the water.</p> <p>If multiple nests are located near each other (within 50 meters), and have similar hatch dates (within 14 days of each other), then closures will encompass all nests in the area and will not be removed until all nests within the closure have hatched.</p>
<b>Nest Watch Program</b>	<p>A cadre of trained volunteers will be established to watch nests that have reached their hatch windows in order to monitor hatchling emergence success and success reaching the water, and to provide for the minimization of negative impacts from artificial lighting, predation, and human disturbance. Depending on the number of nests that may be ready to hatch and the availability of volunteers, it may be necessary for NPS turtle staff to prioritize which nests are watched on any particular night. Priority will be given to watching the nests that are most likely to be negatively impacted by manageable factors.</p>
<b>Nest Relocation</b>	<p>In general, NPS staff will follow guidance in the NCWRC handbook and FWS Loggerhead Sea Turtle Recovery Plan, which is to allow nests to incubate at their original location if there is any reasonable likelihood of survival. Relocation of a nest is considered only as an option of last resort. Accommodation of ORV access shall not be a factor in determining whether a nest needs to be relocated.</p> <p>When relocation is determined to be necessary, nests will be moved toward the dunes immediately behind the original nest location (when possible). Narrow beaches or beaches without nearby dunes (i.e., points and spits) may necessitate relocations to adjacent areas above the high tide line that are free of vegetation. If a choice for a relocation site must be made among adjacent areas that are equally suitable biologically, then accommodation of ORV access to a popular location may be considered as a factor in choosing an appropriate relocation site. An adjacent site that is less suitable biologically shall not be selected for a relocated nest to accommodate ORV access.</p> <p>By Apr 15, Seashore staff will conduct an annual sea turtle nesting habitat assessment to identify areas deemed unsuitable for turtle nests (e.g., those with a high erosion rate) and will discuss with NCWRC prior to nesting season to confirm the high erosion area(s) in which nest relocation would occur during the upcoming nesting season.</p> <p>When a nest is found, designated NPS staff members will assess the need for nest relocation. If it is determined that the nest will NOT be relocated, it will be immediately protected with symbolic fencing and signs approximately 10 × 10 meters in size. Closure size may vary at the discretion of NPS staff depending on the environmental factors at a nest location. If it is determined that the nest will be relocated, NPS will follow relocation procedures identified in the NCWRC handbook. A nest will be relocated only when one or more of the following situations exist:</p> <ul style="list-style-type: none"> <li>• The nest is located at or below the average high tide line, or within an existing “trough” or flooding pool above the average high tide line, where regular inundation or standing water will result in embryonic mortality.</li> <li>• The nest is laid in an area that is known to be susceptible to erosion, as identified by the annual habitat assessment. Such areas typically include the following locations where known erosion or water table issues are known to cause nest mortality, such as spits, points, manmade groins, and re-constructed beaches</li> <li>• When a nest is inspected to verify the presence of eggs and it is found that there are broken eggs in the nest resulting in yolk dripping down into the egg chamber. This situation can result from either predation or human impacts and can result in increased predation if the nest is left in place. NPS staff may “screen” a nest to further discourage additional predation from mammalian predators.</li> <li>• The nest is laid in an area in which unusual, but lawfully conducted, human activities pose a serious threat to nests, such as emergency “beach push” following a major storm event. When these situations arise, NPS will consult with NCWRC prior to conducting these activities to discuss the impact on existing turtle nests.</li> </ul> <p>If a nest is threatened by an imminent storm event, NPS will consult with NCWRC to determine appropriate action.</p>
<b>Strandings</b>	<p>The Seashore will respond to sea turtle strandings in a timely manner, and will forward or report all information, pictures, and signs of human interaction to NCWRC.</p> <p>Necropsies of stranded turtles will be done when possible.</p>
<b>Light Restrictions</b>	<p>From May 1 through Nov 15:</p> <ul style="list-style-type: none"> <li>• Portable lanterns, auxiliary lights, and powered fixed lights of any kind shining for more than 5 minutes at a time would be prohibited on Seashore ocean beaches.</li> <li>• Beach fires would be allowed/restricted as described in the respective alternatives.</li> </ul>
<b>Night-Driving Restrictions</b>	<p>From May 1 until Nov 15 all non-essential vehicle use is prohibited from 9:00 p.m. until 7:00 a.m., except from Sept 16 to Nov 15, ORV routes with no turtle nests remaining will reopen for night driving.</p>
<b>Light Management</b>	<p>By May 1, 2012, turtle-friendly lighting fixtures will be installed on all Seashore structures visible from the ocean beach (except where prevented by other overriding lighting requirements, such as lighthouses, which serve as aids to navigation) and fishing piers operated by NPS concessioners.</p> <p>Educational material will be developed to inform visitors about their impact on the success of sea turtle nests.</p> <p>The Seashore will work with the USFWS, the NCWRC, and Dare County to encourage development of a turtle-friendly lighting education program for villages within the Seashore on Hatteras Island.</p>

Management Activity	Sea Turtles
<b>Adaptive Management Initiatives</b>	<p>The NPS would take an adaptive management approach to the species management program in order to evaluate the effectiveness of and improve the measures identified above. During the course of this plan, the NPS would seek funding and assistance to develop the following adaptive management initiatives for sea turtles:</p> <ul style="list-style-type: none"> <li>• A study to develop a protocol for conducting an artificial lighting survey along the length of the Seashore, which can be used to assess artificial conditions before and after any management actions (such as a lighting ordinance) are implemented to reduce artificial lighting. After light management actions are implemented, levels of lighting will be reassessed and impacts on sea turtle nesting success will be monitored and evaluated.</li> <li>• An adaptive management study to evaluate the level of human disturbance, if any, that might be caused by designating night-driving routes to select points and spits, and to develop management tools to minimize impacts to an acceptable level. If supported by the findings, the NPS will work toward an incremental adjustment (i.e., increase) in nighttime ORV access to limited select locations where not in substantial conflict with turtle nesting and hatchling activity.</li> <li>• An adaptive management study to determine ways to increase the number of male hatchlings that emerge and reach the water. The NPS would seek funding for this study as a conservation measure to contribute to the sea turtle knowledge base pursuant to its <i>Endangered Species Act</i> recovery responsibilities.</li> </ul>
<b>Research</b>	In addition to the species management procedures outlined in this table, through the issuance of a research permit, the NPS may authorize qualified researchers associated with recognized academic or research institutions to conduct additional scientific research on turtle species that will add to the existing knowledge of sea turtles or improve resource protection within the Seashore. Establishment of research areas could be authorized under such a permit.
<b>Implementation of Adaptive Management and Research Initiatives</b>	Should adaptive management initiatives and other research provide information that NPS believes is an adequate basis for management changes, such changes would be evaluated and considered for implementation as part of the 5-year periodic review process.
Management Activity	Seabeach Amaranth
<b>Survey Time and Frequency</b>	<p>Jul to Sep: Before removing any shorebird closures, surveys will be conducted for seabeach amaranth seedlings/plants.</p> <p>Aug: A Seashore-wide annual survey for seabeach amaranth will be conducted in all potential habitats. Some shorebird closures may not be surveyed until just prior to reopening an area to ORV traffic to minimize disturbance of nesting birds or chicks.</p> <p>Observations will end when all known seabeach amaranth plants have died back.</p>
<b>Data Collection</b>	The location of all individual plants or plant clusters will be recorded using GPS. It will be noted whether the plant is located in an area open or closed to recreational use.
<b>Buffers/Closures</b>	<p>Prior to Jun 1, suitable seabeach amaranth habitat will be identified at points and spits where plants have observed within the last 5 years and delineated with symbolic fencing if such areas are not already protected within existing shorebird resource closures.</p> <p>If a plant/seedling is found outside of an existing closure, symbolic fencing with signage will be erected creating a 10- x 10-meter buffer around the plant. If plants are located next to one another, the area will be expanded to create one enclosure protecting several plants.</p> <p>If a seabeach amaranth plant is found during the survey prior to reopening a bird closure to ORV and pedestrian use, the Seashore will protect the plant as described above and reopen the portions of the bird closure where seabeach amaranth plants do not exist.</p> <p>If seabeach amaranth is not present by Sep 1, seabeach amaranth buffers will be removed. If seabeach amaranth is present, buffers will remain until after the plants have senesced, which is typically around Dec 1.</p>
<b>Adaptive Management Initiatives</b>	<p>NPS would take an adaptive management approach to the species management program in order to evaluate the effectiveness of and improve the measures identified above. During the course of this plan, NPS would seek funding and assistance to develop the following adaptive management initiatives for seabeach amaranth:</p> <ul style="list-style-type: none"> <li>• A study to assess the feasibility of seabeach amaranth restoration at up to four suitable sites. NPS would seek funding for this study as a conservation measure to contribute to the seabeach amaranth knowledge base pursuant to its <i>Endangered Species Act</i> recovery responsibilities.</li> </ul>
Management Activity	All Species
<b>Periodic Review</b>	A systematic review of data, annual reports, and other information would be conducted by NPS every 5 years, after a major hurricane, or if necessitated by a significant change in protected species status (e.g., listing or de-listing), in order to evaluate the effectiveness of management actions in making progress toward the accomplishment of stated objectives. Periodic review could result in changes to the management actions in order to improve effectiveness. When desired future conditions for resources are met or exceeded, periodic review and adaptive management may allow for more flexible management of recreational use, provided adverse impacts of such use are effectively managed and wildlife populations remained stable. When progress is not being made toward the attainment of desired future conditions, periodic review and adaptive management may result in increased restrictions on recreational use.

TABLE 11. SHOREBIRD/WATERBIRD BUFFER SUMMARY FOR ALL ALTERNATIVES

Species	Alternative A		Alternative B		Alternatives C, D, and E		Alternative F	
	Breeding Behavior/Nest Buffer	Unfledged Chicks	Breeding Behavior/Nest Buffer	Unfledged Chicks	Breeding Behavior/Nest Buffer (ML1 / ML2)	Unfledged Chicks (ML1 / ML2)	Breeding Behavior/Nest Buffer	Unfledged Chicks
Piping plover	46 meters	183 meters	50 meters	1,000 meters ORV (300 meters for pedestrians)	75 meters / 75 meters	1,000 meters ORV (300 meters for pedestrians)	75 meters	1,000 meters ORV (300 meters for pedestrians)
Wilson's plover	n/a	n/a	n/a	n/a	300 meters / 150 meters	300 meters / 200 meters	75 meters	200 meters
American oystercatcher	Behavior-based	46-91 meters	150 meters	200 meters	300 meters / 150 meters	300 meters / 200 meters	150 meters	200 meters
Least tern	Same as other colonial waterbird	Same as other colonial waterbird	100 meters	200 meters	300 meters / 100 meters	300 meters / 200 meters	100 meters	200 meters
Other colonial waterbird species	Breeding based on behavior/nest 46-91 meters	46-91 meters	200 meters	200 meters	300 meters / 200 meters	300 meters / 200 meters	200 meters	200 meters

Note: Buffers apply to both ORVs and pedestrians, unless otherwise specified.

TABLE 12. ANALYSIS OF HOW ALTERNATIVES MEET OBJECTIVES

Objectives	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Management Methodology</b>						
Identify criteria to designate ORV routes and areas.	Meets objective to some degree. No criteria would be developed to designate routes and areas. The ocean and inlet shoreline and existing soundside routes would potentially be open to ORV use 24 hours a day, year-round.	Meets objective to some degree. No criteria would be developed to designate routes and areas. The ocean and inlet shoreline and existing soundside routes would potentially be open to ORV use, year-round.	Meets objective to a large degree. Routes and areas designated based on seasonal resource and visitor use characteristics of various areas in the Seashore.	Meets objective to a large degree. Routes and areas designated based on providing predictability for visitors and simplified management strategies.	Meets objective to a large degree. Routes and areas designated based on providing a wide variety of access opportunities for all users, while still protecting sensitive resources.	Meets objective to a large degree. Routes and areas designated based on providing a variety of access opportunities for all users, while still protecting sensitive resources. This alternative also provides more predictability than alternative E.
Establish ORV management practices and procedures that have the ability to adapt in response to changes in the Seashore's dynamic physical and biological environment.	Meets objective to a moderate degree. ORV use areas are determined by where resource management closures exist. Flexibility to adapt to changes, but lack of a framework to make these changes efficiently.	Meets objective to some degree. ORV use areas are set through resource management measures under the Consent Decree. Areas are set, but are rigid, and do not have flexibility to adapt as needed to respond to changing environment.	Meets objective to a large degree. Route, areas, and ORV management measures are established that are subject to Periodic Review of both ORV management and species management measures.	Meets objective to some degree. Route, areas, and ORV management measures are established that are subject to Periodic Review and species management measures, but not ORV management measures. The ability to implement safety closures would not be available.	Meets objective to a large degree. Route, areas, and ORV management measures are established that are subject to Periodic Review of both ORV management and species management measures.	Meets objective to a large degree. Route, areas, and ORV management measures are established that are subject to Periodic Review of both ORV management and species management measures.
Establish a civic engagement component for ORV management.	Meets objective to a moderate degree. The Seashore would conduct educational programs during bird and turtle hatching season, which would involve students from public schools, as well as other public involvement activities that engage the public.	Meets objective to a moderate degree. The Seashore would conduct educational programs during bird and turtle hatching season, which would involve students from public schools, as well as other public involvement activities that engage the public.	Meets objective to a large degree as the Seashore would implement more educational programs in local schools, expand the Junior Ranger program, and enlist volunteers for a Sea Turtle Nest Watch Program.	Meets objective to a large degree as the Seashore would implement more educational programs in local schools, expand the Junior Ranger program, and enlist volunteers for a Sea Turtle Nest Watch Program.	Meets objective to a large degree as the Seashore would implement more educational programs in local schools, expand the Junior Ranger program, and enlist volunteers for a Sea Turtle Nest Watch Program.	Meets objective to a large degree as the Seashore would implement more educational programs in local schools, expand the Junior Ranger program, and enlist volunteers for a Sea Turtle Nest Watch Program.
Establish procedures for prompt and efficient public notification of beach access status, including any temporary ORV use restrictions for such things as ramp maintenance, resource and public safety closures, storm events, etc.	Meets objective to some degree. Weekly beach access reports and online news releases provide prompt public notification.	Meets objective to a moderate degree. Weekly beach access reports, online news feeds, and Google Earth maps provide efficient beach access status updates.	Fully meets objective. Weekly beach access reports, online news feeds, and Google Earth maps provide efficient beach access status updates. Implementation of a permit system would provide ORV users with information regarding closed areas.	Fully meets objective. Weekly beach access reports, online news feeds, and Google Earth maps provide efficient beach access status updates. Implementation of a permit system would provide ORV users with information regarding closed areas.	Fully meets objective. Weekly beach access reports, online news feeds, and Google Earth maps provide efficient beach access status updates. Implementation of a permit system would provide ORV users with information regarding closed areas.	Fully meets objective. Weekly beach access reports, online news feeds, and Google Earth maps provide efficient beach access status updates. Implementation of a permit system would provide ORV users with information regarding closed areas.
Build stewardship through public awareness and understanding of NPS resource-management and visitor-use policies and responsibilities as they pertain to the Seashore and ORV management.	Meets objective to some degree. Seashore programs would continue to provide information regarding resource management and aim to build stewardship through public awareness.	Meets objective to some degree. Seashore programs would continue to provide information regarding resource management and aim to build stewardship through public awareness. Public opinion regarding the Consent Decree would detract from these efforts.	Meets objective to a large degree. Seashore programs would continue to provide information regarding resource management and aim to build stewardship through public awareness. Additional programs would be implemented and information provided through the permit system would increase awareness of Seashore resources.	Meets objective to a large degree. Seashore programs would continue to provide information regarding resource management and aim to build stewardship through public awareness. Additional programs would be implemented and information provided through the permit system would increase awareness of Seashore resources.	Meets objective to a large degree. Seashore programs would continue to provide information regarding resource management and aim to build stewardship through public awareness. Additional programs would be implemented and information provided through the permit system would increase awareness of Seashore resources.	Meets objective to a large degree. Seashore programs would continue to provide information regarding resource management and aim to build stewardship through public awareness. Additional programs would be implemented and information provided through the permit system would increase awareness of Seashore resources.

Objectives	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Natural Physical Resources</b>						
Minimize impacts from ORV use to soils and topographic features, for example, dunes, ocean beach, wetlands, tidal flats, and other features.	Meets objective to some degree. ORV use not permitted on dunes, but permitted on the ocean and inlet shoreline and existing soundside routes would potentially be open to ORV use 24 hours a day, year-round. Lack of defined areas likely to lead to increased non-compliance and potential for these resources to be impacted.	Meets objective to a moderate degree. ORV use not permitted on dunes, but permitted on the ocean and inlet shoreline and existing soundside routes would potentially be open to ORV use, year-round. Night-driving restrictions reduce amount of disturbance from beach driving. Implementation of larger buffers and backshore closures would offer protection to resources.	Meets objective to a large degree, as ORV use not permitted on dunes, night-driving restrictions, and carrying capacity limits. However, a large amount of beach open to ORV use could result in impacts to physical resources.	Fully meets objective, as ORV use not permitted on dunes, night-driving restrictions, and beach parking limitations. Least amount of mileage open to ORV use year-round would minimize resource impacts.	Fully meets objectives, as ORV use not permitted on dunes, night-driving restrictions, carrying capacity limits, and soundside driving restrictions.	Meets objective to a large degree, as ORV use not permitted on dunes, night-driving restrictions, and carrying capacity limits. However, a large amount of beach open to ORV use could result in impacts to physical resources
<b>Threatened, Endangered, and Other Protected Species</b>						
Provide protection for threatened, endangered, and other protected species (e.g., state-listed species) and their habitats, and minimize impacts related to ORVs and other uses as required by laws and policies such as the <i>Endangered Species Act</i> , the <i>Migratory Bird Treaty Act</i> , and NPS laws and management policies.	Meets objective to some degree, as temporary resource closures provide protection for sensitive species but buffers would require frequent adjustments to provide adequate protection.	Meets objective to a moderate degree, as increased buffer distances and night-driving restrictions provide increased levels of species protection.	Meets objective to a large degree with increased buffer distances, night-driving restrictions, pet regulations, and SMAs closed to ORV use 7 months per year provide proactive (prior to breeding season) protection.	Fully meets objective with increased buffer distances, night-driving restrictions, pet regulations, and SMAs closed to ORV use year-round providing large areas of resource protection.	Meets objective to a large degree with increased buffer distances, night-driving restrictions, pet regulations, and SMAs closed to ORV use 5.5 months per year provide proactive (prior to breeding season) protection.	Meets objective to a large degree with increased buffer distances, night-driving restrictions, pet regulations, prenesting closures and large, pre-determined buffers for breeding/nesting activity would provide proactive (prior to breeding season) protection.
<b>Vegetation</b>						
Minimize impacts to native plant species related to ORV use.	Meets objective to some degree as driving on dune vegetation is prohibited, but lack of defined ORV areas or backshore closures could result in increased non-compliance and impacts to the resource.	Meets objective to a moderate degree as driving on dune vegetation is prohibited and ocean backshore closures are provided. Sensitive areas with marginal width may be open in the winter that would result in non-compliance problems.	Meets objective to a large degree by adding protective signage at soundside parking areas. Location of ORV corridor at the toe of the dune, with no buffer, may impact vegetation.	Fully meets objective as driving on dune vegetation is prohibited. Year-round SMAs protect large areas, reducing potential impacts to vegetation. ORV corridor would provide a 10 meter buffer from the toe of the dune, further protecting vegetation.	Fully meets objective by closing some soundside access areas and adding protective signage at remaining soundside parking areas. ORV corridor would provide a 10 meter buffer from the toe of the dune, further protecting vegetation.	Meets objective to a large degree by adding protective signage at soundside parking areas. However, there is the potential for damage to vegetation from new soundside access points. Location of ORV corridor at the toe of the dune, with no buffer, may impact vegetation.
<b>Other Wildlife and Wildlife Habitat</b>						
Minimize impacts to wildlife species and their habitats related to ORV use.	Meets objective to some degree, as temporary resource closures provide protection for other wildlife species but buffers are not as large as other alternatives and would not offer large levels of protection.	Meets objective to a moderate degree, as increased buffer distances and night-driving restrictions provide increased levels of species protection, which would include protection to other bird and invertebrate species.	Meets objective to a large degree with increased buffer distances, night-driving restrictions, pet regulations, and SMAs closed to ORV use 7 months per year.	Fully meets objective with increased buffer distances, night-driving restrictions, pet regulations, and SMAs closed to ORV use year-round, which would also offer protection to other bird species and invertebrates.	Meets objective to a large degree with increased buffer distances, night-driving restrictions, pet regulations, and SMAs closed to ORV use 5.5 months per year.	Meets objective to a large degree with increased buffer distances, night-driving restrictions, pet regulations, prenesting closures, and year-round and seasonal VFAs that leave areas of the Seashore less disturbed for wildlife.

Objectives	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Cultural Resources</b>						
Protect cultural resources, such as shipwrecks, archeological sites, and cultural landscapes, from impacts related to ORV use.	Meets objective to some degree as Seashore protections would be put in place for cultural resources, such as shipwrecks, but allowing driving at night and allowing access to large areas of the Seashore would provide for more access to these resources and more possibility for these resources to be disturbed.	Meets objective to a moderate degree as Seashore protection would be in place for cultural resources, such as shipwrecks, and seasonal restrictions on night driving would further limit access to these resources. Large areas of the Seashore would still be accessible by ORV and would provide some level of access to these resources.	Meets objective to a large degree as Seashore protection would be in place for cultural resources, such as shipwrecks, and seasonal restrictions on night driving would further limit access to these resources. Further protection would be provided by the establishment of SMAs that limit access to certain areas of the Seashore during certain times of year and the addition of a permit system that could be revoked for non-compliance, decreasing the probability of drivers taking non-compliant actions.	Meets objective to a large degree as Seashore protection would be in place for cultural resources, such as shipwrecks, and seasonal restrictions on night driving would further limit access to these resources. Further protection would be provided by the establishment of SMAs that limit access to certain areas of the Seashore during certain times of year and the addition of a permit system that could be revoked for non-compliance, decreasing the probability of drivers taking non-compliant actions.	Meets objective to a large degree as Seashore protection would be in place for cultural resources, such as shipwrecks, and seasonal restrictions on night driving would further limit access to these resources. Further protection would be provided by the establishment of SMAs that limit access to certain areas of the Seashore during certain times of year and the addition of a permit system that could be revoked for non-compliance, decreasing the probability of drivers taking non-compliant actions.	Meets objective to a large degree as Seashore protection would be in place for cultural resources, such as shipwrecks, and seasonal restrictions on night driving would further limit access to these resources. Further protection would be provided by the establishment of year-round and seasonal VFAs that limit access to certain areas of the Seashore during certain times of year and the addition of a permit system that could be revoked for non-compliance, decreasing the probability of drivers taking non-compliant actions.
<b>Visitor Use and Experience</b>						
Ensure that ORV operators are informed about the rules and regulations regarding ORV use at the Seashore.	Meets objective to some degree as ORV rules are posted at visitor centers, on ORV ramp bulletin boards, in the park newspaper, and on the website. No permit system would be in place to convey information or provide a mechanism for ensuring regulations are followed.	Meets objective to a moderate degree as ORV rules are posted at visitor centers, on ORV ramp bulletin boards, in the park newspaper, on the website, and within the required night-driving permit.	Fully meets objective as ORV rules are posted at visitor centers, on ORV ramp bulletin boards, in the park newspaper, and on the website. This alternative includes a required education component as part of the ORV permit.	Fully meets objective as ORV rules are posted at visitor centers, on ORV ramp bulletin boards, in the park newspaper, and on the website. This alternative includes a required education component as part of the ORV permit.	Fully meets objective as ORV rules are posted at visitor centers, on ORV ramp bulletin boards, in the park newspaper, and on the website. This alternative includes a required education component as part of the ORV permit.	Fully meets objective as ORV rules are posted at visitor centers, on ORV ramp bulletin boards, in the park newspaper, and on the website. This alternative includes a required education component as part of the ORV permit.
Manage ORV use to allow for a variety of visitor use experiences.	Meets objective to some degree as ORV and VFAs are not officially designated. VFAs occur through seasonal and safety closures throughout the Seashore, but no defined use areas exist to provide for a variety of visitor use experiences.	Meets objective to some degree as ORV and VFAs are not officially designated. VFAs occur through seasonal and safety closures throughout the Seashore, but no defined use areas exist to provide for a variety of visitor use experiences.	Meets objective to a moderate degree as more defined areas for ORV and vehicle free recreational opportunities are provided. New interdunal road access would be provided, offering additional options to ORV users. Some separation of uses and unique opportunities are provided for various user groups.	Meets objective to a moderate degree as more defined areas for ORV and vehicle free recreational opportunities are provided. New interdunal road access would be provided, offering additional options to ORV users. Some separation of uses and unique opportunities are provided for various user groups, but large areas would be closed to all visitors for most of the year, and would not be available to provide for the visitor experience.	Meets objective to a large degree as more defined areas for ORV and vehicle free recreational opportunities are provided. New interdunal road access would be provided, offering additional options to ORV users. Additional user opportunities would be provided including the addition of a park-and-stay options, as well as self-contained vehicle camping. The addition of pedestrian routes, additional parking on the soundside, as well as the potential for water taxi access would all contribute to offering a variety of visitor experiences.	Meets objective to a large degree as more defined areas for ORV and vehicle free recreational opportunities are provided. New interdunal road access would be provided, offering additional options to ORV users. Additional visitor experiences would be provided through pedestrian routes, extra trails, and new parking. Providing some areas of the Seashore that are vehicle-free year-round or seasonally would provide for a greater variety of visitor experiences.

Objectives	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
Minimize conflicts between ORV use and other visitor uses.	Meets objective to some degree as no designated areas for uses are established, which could result in real or perceived conflicts between ORV uses and other visitor uses.	Meets objective to some degree as no designated areas for uses are established, which could result in real or perceived conflicts between ORV uses and other visitor uses.	Meets objective to a large degree as designation of ORV and VFAs would help minimize conflicts. Implementation of a permit system would provide additional education and the ability to revoke permits would likely increase compliance with ORV use regulations and further reduce conflicts. Seasonal night-driving restrictions would also reduce potential visitor use conflicts.	Meets objective to a large degree as designation of ORV and VFAs would help minimize conflicts. Implementation of a permit system would provide additional education and the ability to revoke permits would likely increase compliance with ORV use regulations and further reduce conflicts. Seasonal night-driving restrictions would also reduce potential visitor use conflicts.	Meets objective to a large degree as designation of ORV and VFAs would help minimize conflicts. Implementation of a permit system would provide additional education and the ability to revoke permits would likely increase compliance with ORV use regulations and further reduce conflicts. Seasonal night-driving restrictions would also reduce potential visitor use conflicts.	Meets objective to a large degree as designation of ORV and VFAs would help minimize conflicts. Implementation of a permit system would provide additional education and the ability to revoke permits would likely increase compliance with ORV use regulations and further reduce conflicts. Seasonal night-driving restrictions would also reduce potential visitor use conflicts.
<b>Visitor Safety</b>						
Ensure that ORV management promotes the safety of all visitors.	Meets objective to a moderate degree as ORV safety closures would be provided, as well as right-of-way and unsafe operation regulations contained in the CFR.	Meets objective to a large degree as ORV safety closures would be provided, as well as right-of-way and unsafe operation regulations contained in the CFR. Increased signage, lower speed limits, and increased public awareness would contribute to visitor safety.	Fully meets objective as ORV safety closures would be provided. Reduced speed limits would also apply in all areas. Village beaches would be closed to ORV use during the summer. Permit requirement would provide further information for increasing visitor safety.	Fully meets objective. Although ORV safety closures would not be provided, areas where these occur would be closed year-round as SMAs. Village beaches would be closed to ORVs year-round. Reduced speed limits would also apply in all areas.	Fully meets objective as ORV safety closures would be provided. Reduced speed limits would also apply in all areas. Beach width requirements would limit some ORV use in narrow beach areas and village beaches would be closed to ORV use during the summer.	Fully meets objective. Speed limits, village beach closures, and safety closures would be provided. Also, additional pedestrian safety and right-of-way requirements would provide increased protection.
<b>Seashore Operations</b>						
Identify operational needs and costs to fully implement an ORV management plan.	Meets objective to a large degree as implementation costs have been identified, but carries a degree of uncertainty.	Meets objective to a large degree as implementation costs have been identified, but carries a degree of uncertainty.	Meets objective to a large degree as implementation costs have been identified, but carries a degree of uncertainty.	Meets objective to a large degree as implementation costs have been identified, but carries a degree of uncertainty.	Meets objective to a large degree as implementation costs have been identified, but carries a degree of uncertainty.	Meets objective to a large degree as implementation costs have been identified, but carries a degree of uncertainty.
Identify potential sources of funding necessary to implement an ORV management plan.	Meets objective to a moderate degree. Funding expected under annual budget, but no additional funding source provided.	Meets objective to a moderate degree. Funding expected under annual budget, but no additional funding source provided.	Meets objective to a large degree. Funding expected under annual budget, additional funding would occur by from permit fees utilizing cost recovery.	Meets objective to a large degree. Funding expected under annual budget, additional funding would occur by from permit fees utilizing cost recovery.	Meets objective to a large degree. Funding expected under annual budget, additional funding would occur by from permit fees utilizing cost recovery.	Meets objective to a large degree. Funding expected under annual budget, additional funding would occur by from permit fees utilizing cost recovery.
Provide consistent guidelines, according to site conditions, for ORV routes, ramps, and signage.	Meets objective to some degree. Guidelines are not set and conditions would not be predictable.	Meets objective to a moderate degree. Increased signage would be consistent, but no consistent guidelines for routes and ramps would exist.	Meets objective to a large degree. Guidelines for ramp establishment and maintenance, signage, and routes would be established.	Meets objective to a large degree. Guidelines for ramp establishment and maintenance, signage, and routes would be established.	Meets objective to a large degree. Guidelines for ramp establishment and maintenance, signage, and routes would be established.	Meets objective to a large degree. Guidelines for ramp establishment and maintenance, signage, and routes would be established.

Note: Objectives are measured as fully meets objective, largely meets objective, moderately meets objective, or meets objective to some degree.

TABLE 13. ENVIRONMENTAL IMPACT SUMMARY BY ALTERNATIVE

Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Wetlands and Floodplains</b>						
<b>Wetlands</b>	<b>Impacts of the Alternative on Marine Intertidal Wetlands:</b> Under all alternatives, there would be short term, negligible adverse impacts to marine intertidal wetlands due to continued ORV use in these areas					
	<p><b>Impacts of the Alternative:</b> Under alternative A, there would be long-term minor adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the sound side and along interior ORV routes.</p> <p>There would be no construction (or related impacts) under the no-action alternatives.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wetlands would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Under alternative B, there would be long-term minor adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the sound side and along interior ORV routes.</p> <p>There would be no construction (or related impacts) under the no-action alternatives.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wetlands would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Under alternative C, there would be long-term negligible adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the sound side and along interior ORV routes. Impacts to soundside wetlands would remain at a negligible level due to the protection provided by the installation of signage.</p> <p>Construction activities would avoid wetland areas, resulting in indirect, long-term negligible adverse impacts to wetlands.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wetlands would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Under alternative D, there would be long-term negligible to minor adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the sound side, which would not be protected with signage. Impacts to vegetated wetlands along interior ORV routes would continue.</p> <p>Construction activities would avoid wetland areas, resulting in indirect long-term negligible adverse impacts to wetlands.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wetlands would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Under alternative E, there would be long-term negligible adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the sound side and along interior ORV routes. Impacts to soundside wetlands would remain at a negligible level due to the protection provided by signage and closures of soundside access points.</p> <p>Construction activities would avoid wetland areas, resulting in indirect long-term negligible adverse impacts to wetlands.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wetlands would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Under alternative F, there would be long-term negligible adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the sound side and along interior ORV routes. Impacts to soundside wetlands would remain at a negligible level due to the protection provided by the installation of signage.</p> <p>Construction activities would avoid wetland areas, resulting in indirect long-term negligible adverse impacts to wetlands.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wetlands would be long-term minor to moderate adverse.</p>
<b>Floodplains</b>	<p><b>Impacts of the Alternative:</b> There would be no construction under alternative A. As a result, there would be no impacts to the functions or values of floodplains.</p> <p><b>Cumulative Impacts:</b> No cumulative impacts would occur.</p>	<p><b>Impacts of the Alternative:</b> There would be no construction under alternative B. As a result, there would be no impacts to the functions or values of floodplains.</p> <p><b>Cumulative Impacts:</b> No cumulative impacts would occur.</p>	<p><b>Impacts of the Alternative:</b> Under alternative C, there would be long-term minor adverse impacts to floodplains due to the construction or expansion of seven parking areas in the floodplain.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to floodplains would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Under alternative D there would be long-term negligible adverse impacts to floodplains due to the location of four ORV access ramps in the 100-year floodplain.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to floodplains would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Under alternative E, there would be long-term minor adverse impacts to floodplains due to the construction or expansion of 14 parking areas in the floodplain.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to floodplains would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Under alternative F, there would be long-term minor adverse impacts to floodplains due to the construction or expansion of 12 surfaced and 2 unsurfaced parking areas in the floodplain.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to floodplains would be long-term minor to moderate adverse.</p>

Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Federally Listed Threatened or Endangered Species</b>						
<p><b>Piping Plover</b></p>	<p><b>Impacts of the Alternative:</b> Overall, impacts to piping plover from resource management activities (primarily as a result of surveys and field activities) would be long-term minor to moderate adverse. Although the management of the species would provide a certain level of benefit, the manner in which buffers would be established, along with the need to adjust buffers frequently would have an adverse impact on the species.</p> <p>Overall, impacts to piping plover from ORV and other recreational use would be long-term moderate to major adverse as much of the Seashore would be open to recreational use, with an increased potential that piping plover could be impacted due to disturbance from ORV use and other recreational activities. Lack of a permit system for education and law enforcement, no night-driving restrictions, and lack of compliance with pet leash requirements would contribute substantially to these adverse impacts.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to piping plover would be long-term moderate to major adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, impacts under alternative B from resource management activities (primarily resulting from the effects of surveying and field activities) would be long-term minor to moderate beneficial. Buffers for piping plover would be larger and provide more protection compared to buffers under alternative A. Minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of prenesting closures early in the breeding season, monitoring activities, education and outreach efforts, and establishment of prescribed buffers would provide long-term minor to moderate beneficial impacts to the species.</p> <p>Overall, impacts to piping plover from ORV and other recreational use would be long-term moderate adverse. While some buffers would be increased in an attempt to separate recreational uses from piping plover, access to these buffers would be provided at all Seashore beaches and could result in intentional or un-intentional non-compliance (i.e., when signs are washed out), which would impact the species. Adverse impacts would also occur due to limited prenesting protection outside of the points and spits, and the potential for protective buffers to be reduced during critical life stages of plover chicks.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to piping plover would be long-term moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall impacts under alternative C from resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term moderate beneficial. As with alternative B, minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of SMAs early in the breeding season, monitoring activities, and establishment of prescribed buffers would provide long-term moderate beneficial impacts to the species.</p> <p>Overall, impacts to piping plover from ORV and other recreational use would be long-term minor adverse. The establishment of the SMAs which proactively reduce or preclude recreational use early in the breeding season, ORV permit requirements, seasonal night-driving restrictions, and pet and other recreational activity restrictions would all provide benefits in terms of species protection. As there would still be some opportunity for recreational use to come in contact with and impact piping plovers, and the fact that alternative C would still include some level of pedestrian access to three SMAs during a portion of the breeding season, impacts to piping plover would be long-term minor adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to piping plover would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall impacts to piping plover from resources management activities (primarily resulting from the effects of surveying and field activities) under alternative D would be long-term moderate to major beneficial. As with all species management activities, minor adverse impacts would occur from human presence during monitoring, but on the whole the implementation of SMAs that prohibit ORV use year-round and only allow pedestrian access outside of the breeding season, establishment of prenesting closures early in the breeding season, monitoring activities, and establishment of prescribed buffers would provide long-term moderate to major beneficial impacts to the species.</p> <p>Overall impacts from ORV and other recreational use would be long-term minor adverse. The establishment of SMAs that are closed to ORVs year-round and managed under ML1 procedures during the breeding season would proactively preclude recreational use early in the breeding season from large areas of the Seashore, which would reduce the potential for disturbance to plovers during critical life stages. This protection, combined with ORV permit requirements, seasonal night-driving restriction, and pet and other recreational activities restrictions would all provide benefits in terms of species protection. As there would still be some opportunity for recreational use to come in contact with and impact the species, impacts would be long-term minor adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to piping plover would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall impacts under alternative E from resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term moderate beneficial. As with all species management activities, minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of SMAs early in the breeding season, monitoring activities, and establishment of prescribed buffers would provide long-term moderate beneficial impacts to the species.</p> <p>Overall impacts from ORV and other recreational use would be long-term minor to moderate adverse. The establishment of the SMAs which proactively reduce or preclude recreational use early in the breeding season, ORV permit requirements, and pet and other recreational activity restrictions would all provide benefits in terms of species protection. Although there would be benefits from seasonal night-driving restrictions, they would not be as great as other action alternatives because driving after dark (until 10:00 p.m.) would still be occurring, even during seasonal restrictions. The potential for adverse impacts would exist from the park-and-stay option under this alternative. As there would still be some opportunity for recreational use to come in contact with and impact the species, impacts would be long-term minor to moderate adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to piping plover would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall impacts under alternative F from resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term moderate and beneficial for piping plovers. As with all species management activities, minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of prenesting closures, monitoring activities, and establishment of prescribed buffers would provide long-term moderate beneficial impacts to the species. Long-term moderate benefits to nonbreeding populations would be greater under alternative F than under alternatives C or E because of the addition of the year-round VFAs.</p> <p>Overall impacts under alternative F from ORV and other recreational use would be long-term minor to moderate adverse. The establishment of prenesting closures, year-round and seasonal VFAs, ORV permit requirements, and pet and other recreational activity restrictions would all provide benefits in terms of species protection. As alternative F would provide for more flexible access to various areas of the Seashore, the potential for disturbance to piping plover is increased over alternatives C and D, resulting in long-term minor to moderate adverse impacts.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to piping plover would be long-term minor to moderate adverse.</p>

Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Sea Turtles</b>	<p><b>Impacts of the Alternative:</b> Overall, resources management activities under alternative A would have long-term moderate benefits due to the protection provided to sea turtles. Overall, ORV and other recreational use under alternative A would result in long-term major adverse impacts to sea turtles due to the amount of Seashore available for ORV use and the lack of night-driving restrictions.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to sea turtles would be long-term moderate to major adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, resource management activities under alternative B would have long-term moderate benefits due to the protection provided to sea turtles. Although additional restrictions and regulations would help lessen some of the impacts from ORV use and other recreational activities, overall, the impacts would be long-term moderate adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to sea turtles would be long-term moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, resource management activities under alternative C would have long-term moderate to major beneficial impacts due to the added protection provided to sea turtles. Restrictions placed on nonessential, recreational ORV use under alternative C would provide substantial long-term benefits to sea turtles, including seasonal night-driving restrictions that close the beach before dark (7:00 p.m.), some adverse impacts would still occur in areas where their use is allowed. Therefore, overall, ORV and other recreational use would have long-term minor adverse impacts.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to sea turtles would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, similar to alternative C, management activities under alternative D would result in long-term moderate to major beneficial impacts. While restrictions placed on ORV use under alternative D would provide long-term moderate to major beneficial impacts, similar to alternative C, there would still be some level of adverse impact to sea turtles in areas where ORV use and beach fires are allowed; therefore, overall impacts from ORV and other recreational use would be long-term minor adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to sea turtles would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> Management activities would provide long-term moderate to major beneficial impacts to sea turtles. While additional restrictions and regulations would help lessen some of the impacts from ORVs and other recreational activities, overall, the impacts would be long-term moderate adverse from allowing night driving until 10:00 p.m., and due to increased recreational access throughout the Seashore during the turtle nesting season, including a park-and-stay option for ORVs at selected points and spits.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to sea turtles would be long-term moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, resource management activities would provide long-term moderate to major beneficial impacts to sea turtles. While additional restrictions, such as prohibiting night driving from 9:00 p.m. to 7:00 a.m and regulations would help lessen some of the impacts from ORV and other recreational use, overall, the impacts would be long-term minor to moderate adverse, due to not prohibiting night driving prior to 9:00 p.m. and the earlier re-opening of prenesting areas (after shorebird breeding activity has concluded), resulting in increased recreational access throughout the Seashore during the sea turtle nesting season.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to sea turtles would be long-term minor to moderate adverse.</p>
<b>Seabeach Amaranth</b>	<p><b>Impacts of the Alternative:</b> Overall, because of the protection of seabeach amaranth habitat and plants under alternative A, resources management actions would have long-term minor to moderate beneficial impacts, if plants are detected. Overall, ORV and other recreational use under alternative A would have long-term moderate adverse impacts as plants may go undetected and therefore unprotected from this use.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to seabeach amaranth would be long-term moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, because of the protection of seabeach amaranth habitat and plants under alternative B, resources management actions would have long-term minor to moderate beneficial impacts, if plants are detected. Overall, ORV and other recreational use would result in long-term moderate adverse impacts. Slightly more protection would be provided for the species when compared to alternative A, due to shorebird breeding closures being larger and lasting longer.</p> <p><b>Cumulative Impacts:</b> Cumulative to seabeach amaranth would be long-term moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, because of the protection of seabeach amaranth habitat and plants under alternative C, resources management actions would have long-term moderate beneficial impacts to seabeach amaranth as the establishment of SMAs and increased protection for the species would occur compared to alternatives A and B. Overall, ORV and other recreational use would result in long-term minor to moderate adverse impacts. Because of the establishment of SMAs and protection of approximately 40 miles of beach, the adverse impacts under alternative C would likely be long-term minor to moderate adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to seabeach amaranth would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, because of the increased level of protection of seabeach amaranth habitat and plants under alternative D, when compared to other alternatives, resources management actions would have long-term moderate to major beneficial impacts. Overall ORV and other recreational use would result in long-term minor adverse impacts. Because the establishment of SMAs closed to ORVs year-round would protect approximately 40 miles of beach, the adverse impacts under alternative D would be greatly reduced compared to the other alternatives and result in long-term minor adverse impacts.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to seabeach amaranth would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, because of the protection of seabeach amaranth habitat and plants under alternative E, resources management actions would have long-term minor to moderate beneficial impacts as ORV access to more areas would be allowed during the germination period, than under action alternatives C and D. Overall, ORV and other recreational use would have long-term minor to moderate adverse impacts to seabeach amaranth due to the increased level of recreational access allowed when compared to the other action alternatives.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to seabeach amaranth would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, because of the protection of seabeach amaranth habitat and plants under alternative F, resources management actions would have long-term minor to moderate beneficial impacts as ORV access to more areas would be allowed during the germination period, than under action alternatives C and D. Overall, ORV and other recreational use would be similar to those under alternative E and result in long-term minor to moderate adverse impacts to seabeach amaranth.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to seabeach amaranth would be long-term minor to moderate adverse.</p>

Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>State-Listed and Special Status Species</b>						
<b>American Oystercatcher</b>	<b>Impacts of the Alternative:</b> Impacts would be long-term minor to moderate adverse as surveying and lack of specific prenesting closures for this species may miss early nesters. Piping plover prenesting closures, which could be utilized by this species as well, would not protect a number of American oystercatcher nest sites used in recent years. Also, buffer distances based on bird behavior may not provide adequate protection for the species.	<b>Impacts of the Alternative:</b> Establishment of piping plover prenesting closures earlier in the season that could be used by oystercatchers and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts related to human disturbance during field activities, resources management activities on the whole would provide information and result in actions that would be beneficial to the species.	<b>Impacts of the Alternative:</b> Implementation of 10 SMAs that are closed to ORVs during the breeding season would provide a proactive resource closure early in the breeding season. Establishment of prenesting closures earlier in the season and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts related to human disturbance during field activities, on the whole, resources management activities would provide information that would enable the implementation of adaptive management initiatives and contribute to better management. These activities would result in long-term beneficial impacts to the American oystercatcher, greater than those provided under alternative B.	<b>Impacts of the Alternative:</b> Establishment of 10 SMAs that are closed to ORVs year-round and all managed under ML1 procedures during the breeding season would provide long-term benefits to breeding and wintering American oystercatchers, greater than those under alternative C. Additional benefits would be provided from surveying and closures outside of these established SMAs, as well as from the education and outreach provided. These surveying and field activities would provide information that would enable the implementation of adaptive management initiatives and contribute to better management. These activities would result in long-term beneficial impacts to this species, greater than those provided under alternative B.	<b>Impacts of the Alternative:</b> Implementation of 10 SMAs, 7 of which are closed to ORVs during the breeding season, would provide a proactive resource closure early in the breeding season. Establishment of prenesting closures earlier in the season and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts from human disturbance during field activities, resources management activities on the whole would provide information that would enable the implementation of adaptive management initiatives and contribute to better management. These activities would result in long-term beneficial impacts to this species, greater than those provided under alternative B.	<b>Impacts of the Alternative:</b> Implementation of prenesting closures would provide a proactive resource closure early in the breeding season. Seasonal and year-round VFAs that total 39 miles of Seashore would provide additional areas with less disturbance for shorebirds. Establishment of prenesting closures earlier in the season and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts related to human disturbance during field activities, resources management activities on the whole would provide information that would enable the implementation of adaptive management initiatives and contribute to better management. These activities would result in long-term beneficial impacts to the species, greater than those provided under alternative B.

Table 13. Environmental Impact Summary by Alternative

Impact Topic	Alternative A: No Action— Continuation of Management under the Interim Strategy	Alternative B: No Action— Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>American Oystercatcher (continued)</b>	Impacts would be long-term moderate to major adverse as buffers that adjust frequently based on bird behavior are more subject to non-compliance. The lack of designated VFAs, a permitting system, carrying capacity, or seasonal night-driving restrictions, and allowing pets at the Seashore during breeding season would contribute to these adverse impacts.	Establishment of prenesting closures for piping plover earlier in the season, implementation of larger, more immediate buffers, longer lasting closures for American oystercatchers once breeding behavior occurs, and night-driving restrictions would benefit the American oystercatcher. However, recreational use, with no carrying capacity, would still occur in the vicinity of this species and the established buffers may not be large enough to afford adequate protection. Because the birds would not be under constant observation, disturbance may go undetected and implementation of adequate buffers may be delayed in some nesting locations. Compliance with closures may not be absolute, resulting in minor to moderate adverse impacts if non-compliance occurs. Further adverse impacts would result from allowing pets in the Seashore during breeding season, resulting in the possibility of non-compliance with these regulations. Because of these factors, impacts to American oystercatchers from ORV use and other recreational activities would be long term moderate adverse.	Implementation of a permit system with an educational component, larger buffer sizes, seasonal night-driving restrictions, establishment of breeding and nonbreeding SMAs, and not allowing pets in SMAs would benefit the American oystercatcher. SMAs would provide a proactive method of limiting recreational uses early in the breeding season, and limit the potential for impacts to state-listed/special status species. However, alternative C does manage three SMAs under ML2 procedures, which provide for some level of pedestrian access into these areas, and introduces the potential for impacts to the species. Although there would be some protection measures in place, ORV and other recreational use could still have impacts to the species, resulting in long-term minor to moderate adverse impacts to American oystercatchers.	Providing large SMAs that are closed year-round to ORVs and closed to pedestrians during the breeding season would provide large undisturbed areas for both breeding and nonbreeding oystercatchers. Further benefits would be provided by seasonal night-driving restrictions, the establishment of a permit system with an educational component, and prohibition of pets in SMAs year-round. With these measures in place, impacts to American oystercatchers from ORV and other recreational use would be long-term minor adverse, as the chance of disturbance still exists, but would be lower than that under the other alternatives evaluated.	Implementation of a permit system with an educational component, larger buffer sizes, seasonal night-driving restrictions, restrictions on pets in SMAs, and establishment of breeding and nonbreeding SMAs would benefit the American oystercatcher. SMAs would provide a proactive method of limiting recreational uses early in the breeding season, and limit the potential for impacts to state-listed/special status species. However, alternative E does allow an ORV access corridor at three SMAs managed under ML2 procedures during the breeding season (more than the other action alternatives), which provide for some level of pedestrian or ORV access into these area, which introduces the potential for impacts to the species. Although there would be some protection measures in place, recreational use could still result in long-term minor to moderate adverse impacts to American oystercatchers.	Implementation of a permit system with an educational component, prenesting closures, seasonal night-driving restrictions, allowing pets under the regulations of 36 CFR 2.15 with the additional prohibition of pets in resource closures and in pedestrian shoreline access areas in front of (i.e., seaward of) bird prenesting areas and establishment of seasonal and year-round VFAs that total 39 miles of Seashore would benefit the American oystercatcher. Prenesting closures would provide a proactive method of limiting recreational uses early in the breeding season, and limit the potential for impacts to state-listed/special status species, with additional areas that are relatively less disturbed provided by prenesting closures. However, alternative F does manage all areas of the Seashore to allow for ORV and/or pedestrian access, which introduces the potential for impacts to the species. As there would be some protection measures in place, but recreational use could still have impacts to the species, impacts to American oystercatchers would be long-term minor to moderate adverse.

Impact Topic	Alternative A: No Action— Continuation of Management under the Interim Strategy	Alternative B: No Action— Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<p><b>Colonial Waterbirds</b></p>	<p><b>Impacts of the Alternative:</b> Impacts would be long-term minor to moderate adverse as no prenesting closures would be established for colonial waterbirds. Some species, such as terns and black skimmers, may be able to utilize the prenesting closures established for piping plovers; however, those prenesting areas would not protect a number of colonial waterbird nest sites used in recent years. Also, buffer distances based on bird behavior may not provide adequate protection for the species.</p> <p>Impacts would be long-term moderate to major adverse as buffers may not be adequate to protect the species, and disturbance from recreational uses is more likely. The lack of designated VFAs, a permitting system, carrying capacity, or seasonal night-driving restrictions, and allowing pets in the vicinity of breeding birds would also contribute to adverse impacts.</p>	<p><b>Impacts of the Alternative:</b> Establishment of piping plover prenesting closures earlier in the season that would be used by some colonial waterbird species and establishment of larger, pre-set buffers would result in long-term beneficial impacts to colonial waterbirds. While there would still be minor adverse impacts related to human disturbance during field activities, resources management activities on the whole would provide information and result in actions that would be beneficial to the species.</p> <p>Impacts to colonial waterbirds from ORV and other recreational use would be long-term moderate adverse, for the same reasons as American oystercatchers under this alternative.</p>	<p><b>Impacts of the Alternative:</b> Impacts to colonial waterbirds from surveying and field activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers.</p> <p>Impacts to colonial waterbirds from ORV and other recreational use would be long-term minor to moderate adverse, for the same reasons as American oystercatchers under this alternative.</p>	<p><b>Impacts of the Alternative:</b> Impacts to colonial waterbirds from surveying and field activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers.</p> <p>Impacts to colonial waterbirds from ORV and other recreational use would be long-term minor adverse, for the same reasons as American oystercatchers under this alternative.</p>	<p><b>Impacts of the Alternative:</b> Impacts to colonial waterbirds from resources management activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers.</p> <p>Impacts to colonial waterbirds from ORV and other recreational use would be long-term minor to moderate adverse, for the same reasons as those discussed above for American oystercatchers under this alternative.</p>	<p><b>Impacts of the Alternative:</b> Impacts to colonial waterbirds from resources management activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers.</p> <p>Impacts to colonial waterbirds from ORV and other recreational use would be long-term minor to moderate adverse, for the same reasons as American oystercatchers under this alternative.</p>

Table 13. Environmental Impact Summary by Alternative

Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<p><b>Wilson’s Plover</b></p>	<p><b>Impacts of the Alternative:</b>                      Impacts would be long-term minor adverse as the habitat for this species would be well surveyed during piping plover surveys and this species would be able to take advantage of management measures for piping plover as their breeding seasons and habitat requirements are similar. Also, buffer distances based on bird behavior may not provide adequate protection for the species. Some benefits may occur from incidental management of Wilson’s plover during piping plover management activities, both during breeding and nonbreeding seasons.</p> <p>Impacts would be long-term moderate to major adverse as no specific management would be provided for this species, although they could utilize buffers and closures established for piping plover. The lack of designated VFAs, a permitting system, carrying capacity, or seasonal night-driving restrictions, and allowing pets at the Seashore during breeding season would contribute to these adverse impacts.</p>	<p><b>Impacts of the Alternative:</b>                      Establishment of piping plover prenesting closures earlier in the season that could be used by other species and establishment of larger, pre-set buffers for piping plover, used by Wilson’s plover, would result in long-term beneficial impacts to Wilson’s plover. While there would still be minor adverse impacts related to human disturbance during field activities, species surveying and field activities on the whole would provide information and result in actions that would be beneficial to the species.</p> <p>Impacts to Wilson’s plover from ORV and other recreational use would be long-term minor to moderate adverse. Although this species would face the same adverse impacts as American oystercatchers and colonial waterbirds, it also tends to utilize closures for piping plover and would therefore be provided slightly more protection than other state-listed/special status species.</p>	<p><b>Impacts of the Alternative:</b>                      Impacts to Wilson’s plover from surveying and field activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers, with slightly greater benefits as this species would also benefit from the management measures applied to piping plover.</p> <p>Impacts to Wilson’s plover from ORV and other recreational use would be long-term minor adverse, less than those under alternative A and B. Although this species would face the same adverse impacts as American oystercatchers and colonial waterbirds, it also tends to utilize the closures for piping plover, in addition to the specific buffers/closures provided for the species, and would therefore be provided slightly more protection than other state-listed/special status species.</p>	<p><b>Impacts of the Alternative:</b>                      Impacts to Wilson’s plover from surveying and field activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers, with slightly greater benefits as this species would also benefit from the management measures applied to piping plover.</p> <p>Impacts to Wilson’s plover from ORV and other recreational use would be long-term negligible to minor adverse. Although this species would face the same adverse impacts as American oystercatchers and colonial waterbirds, it also tends to utilize closures for piping plover, in addition to the buffers/closures provided specifically for this species, and would therefore be provided slightly more protection than other state-listed/special status species.</p>	<p><b>Impacts of the Alternative:</b>                      Impacts to Wilson’s plover from resources management activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers, with slightly greater benefits as this species would also benefit from the management measures applied to piping plover.</p> <p>Impacts to Wilson’s plover from ORV and other recreational use would be long-term minor adverse. Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Red Knot</b>	<b>Impacts of the Alternative Common to All:</b> Many of the surveying and field activities for other species would occur outside of the primary time when the red knot is a resident at the Seashore. Therefore, any impacts to this species from surveying and field activities for other species would be long-term negligible adverse.					
	<p>Impacts to nonbreeding red knot would be long-term minor adverse as their prime foraging habitat (ocean shoreline) would not be afforded protection by nonbreeding closures, although the ability of this species to use wintering closures for piping plover at inlets and Cape Point would result in some benefit.</p> <p>Impacts would be long-term moderate adverse as no specific management would be provided for this species especially during a key life stage of wintering. The lack of designated VFAs, a permitting system, or night-driving restrictions when red knots are at the Seashore, and allowing pets at the Seashore during the migrating/nonbreeding season would contribute to these adverse impacts. Impacts to red knots would be lower than other species as they would not be subject to impacts during their breeding cycle and their use of the Seashore corresponds to times of lower visitation.</p>	<p>The red knot would benefit from extended breeding season closures for other species and from wintering closures for piping plover at the inlets and Cape Point. Impacts to nonbreeding red knot would be long-term minor adverse as their prime foraging habitat (ocean shoreline) would not be afforded protection by nonbreeding closures.</p> <p>Impacts to red knots from ORV and other recreational use would be long-term moderate adverse as no specific management would be provided for this species especially during a key life stage of wintering. Although this species may benefit from longer lasting breeding season closures for other species and from winter closures established for piping plovers, the lack of designated VFAs, a year-round permitting system, no night-driving restrictions when red knots are at the Seashore, and allowing pets at the Seashore during the migrating / nonbreeding season would contribute to these adverse impacts.</p>	<p>Nonbreeding Shorebird SMAs and the establishment of VFAs along the ocean shoreline would result in beneficial impacts to nonbreeding red knots. However, the ability of this species to use wintering closures that have been established for piping plover as well as the establishment of SMAs, some of which are closed to ORVs year-round, would be beneficial to those red knot that happen to use those areas, and overall result in long-term beneficial impacts to the species when compared to alternatives A and B.</p> <p>Impacts to red knot from recreation and other activities would be long-term minor adverse due to the additional nonbreeding closures provided under alternative C that offer this wintering species further protection.</p>	<p>Nonbreeding Shorebird SMAs and the establishment of VFAs along the ocean shoreline would result in beneficial impacts to nonbreeding red knots. However, the ability of this species to use wintering closures that have been established for piping plover as well as the establishment of SMAs, all of which are closed to ORVs year-round would result in long-term beneficial impacts to red knot when compared to all other alternatives.</p> <p>Impacts to red knot from recreation and other activities would be long-term negligible to minor adverse due to the additional nonbreeding closures provided under alternative D that offer this wintering species further protection, as well as the large year-round SMAs that would offer further protection during red knot wintering.</p>	<p>The ability of this species to use wintering closures that have been established for piping plover as well as the establishment of SMAs, some of which are closed year-round, would be beneficial, and overall result in long-term beneficial impacts to the species when compared to alternatives A and B.</p> <p>Impacts to red knot from ORV and other recreational use would be long-term minor adverse due to the additional nonbreeding closures provided under alternative E that offer this wintering species further protection; however, there would be greater adverse impacts than under alternatives D or F due to fewer miles of shoreline being closed to ORVs under alternative E during the nonbreeding season.</p>	<p>The ability of this species to use wintering closures that have been established for piping plover as well as the establishment of year-round and seasonal VFAs over 39 miles of the Seashore (of which 26 miles would be year-round and provide protection of nonbreeding habitat) would be beneficial, and overall result in long-term beneficial impacts to the species when compared to alternatives A and B.</p> <p>Impacts to red knot from ORV and other recreational use would be long-term minor adverse due to the wintering closures established for piping plover, as well as the 26 miles of year-round VFAs that provide less disturbed nonbreeding habitat.</p>
<b>All State-Listed and Special Status Species</b>	<p><b>Cumulative Impacts (for all State-listed and Special Status Species):</b> Cumulative impacts to state-listed and special status species would be long-term moderate to major adverse.</p>	<p><b>Cumulative Impacts (for all State-listed and Special Status Species):</b> Cumulative impacts to state-listed and special status species would be long-term moderate adverse.</p>	<p><b>Cumulative Impacts (for all State-listed and Special Status Species):</b> Cumulative impacts to state-listed and special status species would be long-term minor to moderate adverse.</p>	<p><b>Cumulative Impacts (for all State-listed and Special Status Species):</b> Cumulative impacts to state-listed and special status species would be long-term minor adverse.</p>	<p><b>Cumulative Impacts (for all State-listed and Special Status Species):</b> Cumulative impacts to state-listed and special status species would be long-term minor to moderate adverse.</p>	<p><b>Cumulative Impacts (for all State-listed and Special Status Species):</b> Cumulative impacts to state-listed and special status species would be long-term minor to moderate adverse.</p>

Impact Topic	Alternative A: No Action— Continuation of Management under the Interim Strategy	Alternative B: No Action— Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Wildlife and Wildlife Habitat - Other Bird Species</b>	<b>Impacts of the Alternative Common to All:</b> Many of the surveying and field activities for protected species would occur outside of the primary time when other bird species are residents at the Seashore. Therefore, any impacts to other bird species from surveying and field activities for protected species would be long-term negligible adverse.					
	<p><b>Impacts of the Alternative:</b> Impacts to other bird species from resources management activities would be long-term minor adverse as nonbreeding closures would not be species-specific and therefore would not protect important habitat areas such as the ocean shoreline. Impacts of ORV and other recreational use would be long-term moderate adverse as no specific management would be provided for this species, increasing the possibility of disturbance to the species from recreational use. The lack of designated VFAs, a permitting system, or night-driving restrictions during the time period when these species are present at the Seashore, and allowing ORVs, people and pets at the Seashore during the nonbreeding season in the vicinity of these species would contribute to adverse impacts.  There would be no construction and therefore no construction-related to disturbance to other bird species under the no-action alternatives.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wildlife and wildlife habitat (other bird species) would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Impacts to other bird species would be long-term minor adverse as nonbreeding closures would not be species-specific and therefore would not protect important habitat areas such as the ocean shoreline when many of these species are wintering or migrating. Impacts of ORV and other recreational use would be long-term moderate adverse as no specific management would be provided for this species, increasing the possibility of disturbance to the species from recreational use. The lack of designated VFAs, allowing night driving during the time period when other bird species are present at the Seashore, and allowing ORVs, people and pets at the Seashore during the nonbreeding season in the vicinity of these species would contribute to adverse impacts.  There would be no construction and therefore no construction-related to disturbance to other bird species under the no-action alternatives.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wildlife and wildlife habitat (other bird species) would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> The establishment of both breeding and nonbreeding SMAs, some of which are closed to ORVs year-round, would result in long-term beneficial impacts to other bird species when compared to alternatives A and B. Impacts from ORV and other recreational use would be long-term minor adverse due to the additional nonbreeding closures provided under alternative C that offer wintering species further protection.  Impacts to other bird species from construction activities would be short-term negligible to minor and adverse due to temporary displacement during construction activities.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wildlife and wildlife habitat (other bird species) would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> The establishment of SMAs, which would be closed to ORVs year-round, would result in long-term beneficial impacts to other bird species. Beneficial impacts would be greater than those under alternative C due to the amount of mileage closed to ORV use year-round. ORV and other recreational use would result in long term negligible to minor adverse impacts to other bird species due to the amount of beach closed to ORV use and the additional nonbreeding closures that offer wintering species further protection.  Impacts to other bird species from construction activities would be short-term negligible to minor and adverse due to temporary displacement during construction activities.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wildlife and wildlife habitat (other bird species) would be long-term negligible to minor adverse.</p>	<p><b>Impacts of the Alternative:</b> The establishment of both breeding and nonbreeding SMAs, some of which are closed to ORVs year-round, would result in long-term beneficial impacts to other bird species. ORV and other recreational use would result in long term minor adverse impacts to other bird species due to additional nonbreeding closures provided under alternative E that offer species further protection, with greater adverse impacts than under alternatives D or F from fewer miles of shoreline being closed to ORVs under alternative E during the nonbreeding season. Adverse impacts would be greater than those under alternatives C or D due to the increased level of recreational access provided under alternative E.  Impacts to other bird species from construction activities would be short-term negligible to minor and adverse due to temporary displacement during construction activities.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wildlife and wildlife habitat (other bird species) would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> The establishment of prenesting areas, seasonal and year-round VFAs, and wintering habitat closures would result in long-term beneficial impacts to other bird species. Additional benefits, when compared to the other alternatives, would be realized under alternative F from nonbreeding closures as well as the 26 miles of year-round VFAs that would provide protection during this time. Impacts to other bird species from ORV and other recreational use would be long-term minor adverse due to the additional nonbreeding closures provided under alternative F that offer wintering species further protection.  Impacts to other bird species from construction activities would be short-term negligible to minor and adverse due to temporary displacement during construction activities.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wildlife and wildlife habitat (other bird species) would be long-term minor adverse.</p>

Wildlife and Wildlife Habitat - Invertebrates	<b>Impacts of the Alternative Common to All:</b> The use of vehicles to conduct resources management activities would result in long-term negligible adverse impacts to invertebrates due to the potential for mortality of individual invertebrate species.					
	<p><b>Impacts of the Alternative:</b> Recreational ORV use would result in long-term minor to moderate adverse impacts to invertebrate species primarily due to mortality arising from unlimited night driving in the intertidal and wrack areas.</p> <p>There would be no construction and therefore no construction-related to disturbance to invertebrates under the no-action alternatives.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wildlife and wildlife habitat (invertebrates) would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Recreational ORV use would result in long-term minor adverse impacts to invertebrate species resulting from the continued use of ORVs in invertebrate habitat. Impacts would be reduced when compared to alternative A due to limitations on ORV use at night and within the larger resources management closures under alternative B.</p> <p>There would be no construction and therefore no construction-related to disturbance to invertebrates under the no-action alternatives.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wildlife and wildlife habitat (invertebrates) would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Recreational ORV use would result in long-term negligible to minor adverse impacts to invertebrate species resulting from the continued use of ORVs in invertebrate habitat. Impacts would be reduced due to longer seasonal restrictions on vehicle use under alternative C.</p> <p>Short term negligible adverse impacts to invertebrates would occur due to temporary displacement during construction activities.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wildlife and wildlife habitat (invertebrates) would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> Recreational ORV use would result in long-term negligible adverse impacts to invertebrate species resulting from the continued use of ORVs in invertebrate habitat. Impacts to invertebrates would be reduced under this alternative due to the amount of beach closed to recreational use.</p> <p>Short term negligible adverse impacts to invertebrates would occur due to temporary displacement during construction activities.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to wildlife and wildlife habitat (invertebrates) would be long-term negligible to minor adverse.</p>	<p><b>Impacts of the Alternative:</b> Recreational ORV use would result in long-term minor adverse impacts to invertebrate species resulting from the continued use of ORVs in invertebrate habitat. Table 13. Environmental Impact Summary by Alternative

Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Soundscapes</b>	<p><b>Impacts of the Alternative:</b> Overall, minor to moderate impacts, depending upon vehicle speed, would occur along the beaches where most routes are established for ORV driving. While impacts over the majority of the Seashore beaches would be long-term adverse due to greater numbers of designated year-round ORV routes, impacts would be short-term adverse in the areas in front of village beaches, which are only opened seasonally to ORV use. Short-term adverse impacts would also result during other closure periods along any ORV route for resource protection, safety or administrative purposes. During closures, the potential for increased vehicle concentrations along remaining open ORV routes would increase the frequency of occurrence of single ORV pass-by events. Impacts would remain minor to moderate adverse, depending on vehicle speed, but vehicle noise may dominate the natural soundscape more frequently. In general, as ORV use would continue intermittently over the life of the management plan, vehicle noise would be a recurring, long-term minor to moderate adverse impact in all areas of the Seashore beaches open to ORV driving. Additionally, as closure periods, which have the potential to provide short-term benefits, would be implemented throughout the life of the management plan, long-term benefits would arise. As noise from ORV use would add at least 3 decibels (A-weighted scale) (dBA) to the natural ambient sound levels within the Seashore, wildlife would also experience adverse impacts.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to soundscapes would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> As described under alternative A, impacts to the natural soundscape within the Seashore would be minor to moderate, depending upon vehicle speed. Due to the slower speed limits proposed during the peak season when more visitors would be using beach areas, the potential for a greater reduction in visitor awareness would occur under this alternative as compared to alternative A. On beaches where ORV routes are open year-round, including the additional year-round route established under alternative B, impacts would be long-term and adverse, but would potentially become short-term adverse during closure periods. In locations where ORV routes are specifically designated as “seasonal,” impacts would be short-term adverse. As with alternative A, closures of any kind present the potential for increased concentrations of vehicles in areas where ORV routes remain open. In such areas, the potential for vehicle noise to more frequently dominate the sound energy would arise. Aside from the short-term benefits that would occur in areas undergoing closure periods of any kind, additional short-term benefits may occur under alternative B as a result of regulations imposed to seasonally eliminate night driving. Impacts to wildlife would be similar to those under alternative A.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to soundscapes would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> As described under alternative B, impacts to the natural soundscape resulting from a 15 mph speed limit would be minor adverse. However, the potential for wildlife and visitor use impacts, as well as the extent of such impacts, may be reduced due to seasonal restrictions and designated VFAs. Like under alternatives A and B, impacts would be long-term adverse for year-round ORV areas, potentially becoming short-term subject to temporary resource closures. As seasonal closures would limit ORV activity to less than a year, short-term adverse impacts would result. Closures of any kind, depending on the closure length, would also provide short-term benefits by providing noise-free periods. Under alternative C there would be areas of negligible impacts due to designated VFAs and greater opportunities for natural sounds to prevail due to longer seasonal closure periods as compared to alternatives A and B. Conversely, fewer open ORV areas and longer seasonal closure periods also present the potential for greater concentrations of ORVs in areas with open ORV routes, thereby increasing the frequency of vehicle noise in such areas. Construction activities would be localized and of short duration and would be minor adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to soundscapes would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> As described under alternative A, impacts to the natural soundscape resulting from a 15 mph speed limit would be minor adverse. However, the potential for impacts to wildlife and visitor use from ORV noise would be the least under this alternative, as compared to the no-action and all action alternatives due to larger areas of designated vehicle free use. During resource closures, short-term benefits would occur due to the lack of ORV noise and would also be long-term benefits since closures would recur throughout the life of the management plan. The key difference between this alternative and all other alternatives is that alternative D has the greatest extent of long-term negligible adverse impacts resulting from the number of year-round vehicle-free designations. Alternative D also has the greatest extent of long-term benefits to the natural soundscape, visitors and wildlife due to these VFAs. However, this alternative would also present the greatest potential for increased ORV pass-by events that dominate the sound energy in designated ORV areas due to the fewer number of open ORV areas in which vehicles may drive. Like under alternative C, construction related noise impacts from ramp improvements and the construction of a new ramp would be minor adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to soundscapes would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> As described under alternative A, impacts to the natural soundscape on the beaches resulting from a 15 mph speed limit would be minor adverse. However, like under alternative C, the potential for wildlife and visitor use impacts, as well as the extent of such impacts, may be reduced due to seasonal restrictions and designated VFAs. On the other hand, pass-through zones and earlier openings along seasonal routes under this alternative would potentially provide fewer “noise-free” periods for visitors and wildlife. Vehicle diversions to other open routes may not be as frequent under this alternative as under alternative C or D given that some seasonal routes are open longer than others, ORV pass-through zones would be established in certain areas, and water taxi service would be available as an alternative option to driving. Although under this alternative, more ramps would be constructed, as compared to alternatives C and D, construction-related impacts would remain minor adverse due to the localized nature and short duration of the activities.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts under alternative E would be long-term minor adverse.</p>	<p><b>Impacts of the Alternative:</b> As described under alternative A, impacts to the natural soundscape on the beaches resulting from a 15 mph speed limit would be minor adverse. Like under alternatives C and E, the potential for wildlife and visitor use impacts from ORV noise may be reduced due to seasonal closures and designated VFAs. “Noise-free” periods would be greater than alternatives C and E. Vehicle diversions to other open routes may not be as frequent under this alternative as under the other action alternatives given that some seasonal routes are open longer than others. Although under this alternative, more ramps would be constructed, as compared to alternatives C and D, construction-related impacts would remain minor adverse due to the localized nature and short duration of the activities.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts under alternative F would be long-term minor adverse.</p>

Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<p><b>Visitor Use and Experience</b></p>	<p><b>Impacts of the Alternative:</b>                      Those looking for an experience at the Seashore that includes ORV use would have long-term negligible to minor adverse impacts as some areas would be closed for resource protection, but alternative A would provide the most ORV access of any alternative. Should there be extensive resource closures in a given year, the potential for long-term moderate impacts exists. Those looking for a vehicle free experience at the Seashore would experience long-term moderate adverse impacts as alternative A does not provide for a specific separation of uses or designation of VFAs. Since night driving would be permitted under alternative A, there would be short-term minor adverse impacts to night skies.</p> <p><b>Cumulative Impacts:</b>                      Cumulative impacts would be long-term negligible to minor adverse for ORV users and long-term, moderate, and adverse for visitors who desire a vehicle free beach experience.</p>	<p><b>Impacts of the Alternative:</b>                      Those looking for an experience at the Seashore that includes ORV use would have long-term moderate to major adverse impacts as one or more spit or point would be closed for an extended period of time during the breeding season. During the remainder of the year, there would be negligible to minor adverse impacts to ORV users as limited areas would be closed for resource protection. Those looking for a vehicle free experience at the Seashore would experience long-term moderate adverse impacts as alternative B does not provide for a specific separation of uses outside of seasonal ORV closures of village beaches and no VFAs would be designated. Since night driving would be seasonally restricted under alternative B, there would be long-term negligible to minor adverse impacts to night skies, with long-term beneficial impacts during times of seasonal night-driving restrictions.</p> <p><b>Cumulative Impacts:</b>                      Cumulative impacts would be long-term moderate to major adverse for ORV users, and long-term moderate adverse for visitors who desire a vehicle free beach experience.</p>	<p><b>Impacts of the Alternative:</b>                      Those looking for an experience at the Seashore that includes ORV use would have long-term moderate to major adverse impacts as the designation of VFAs and the establishment of the SMAs would seasonally preclude ORV use from some areas of the Seashore that are popular ORV use areas. While three areas managed under ML2 procedures would have pedestrian access corridors, no ORV corridors would be provided in the SMAs, resulting in greater impacts to ORV users. Those looking for a vehicle free experience at the Seashore would experience long-term benefits as alternative C provides for pedestrian corridors in three SMAs under ML2 procedures, as well as providing additional VFAs. Since night driving would be seasonally restricted under alternative C, there would be long-term negligible to minor adverse impacts to night skies, with long-term beneficial impacts during times of seasonal night-driving restrictions.</p> <p><b>Cumulative Impacts:</b>                      Cumulative impacts would be long-term moderate to major adverse to ORV users, and long-term beneficial for visitors who desire a vehicle free beach experience.</p>	<p><b>Impacts of the Alternative:</b>                      Those looking for an experience at the Seashore that includes ORV use would have long-term major adverse impacts as all SMAs and village beaches would be designated as VFAs year-round, which would prohibit the use of ORV in many popular visitor use areas. Those looking for a vehicle free experience at the Seashore would experience long-term benefits as alternative D provides for many designated VFAs throughout the Seashore, although pedestrian access would be prohibited in the SMAs during the breeding season. Since night driving would be seasonally restricted under alternative D, there would be long-term negligible to minor adverse impacts to night skies, with long-term beneficial impacts during times of seasonal night-driving restrictions.</p> <p><b>Cumulative Impacts:</b>                      Cumulative impacts would be long-term major and adverse to ORV users, and long-term beneficial for visitors who desire a vehicle free beach experience.</p>	<p><b>Impacts of the Alternative:</b>                      Those looking for an experience at the Seashore that includes ORV use would have long-term moderate adverse impacts as the designation of VFAs and the establishment of the SMAs would preclude ORV use, either seasonally or year-round, from some areas of the Seashore that are popular visitor use areas. Three SMAs under ML2 management procedures would provide an ORV pass-through corridor at the start of the breeding season, subject to resource closures, lessening the impacts to this user group. Additional recreational opportunities such as park-and-stay and SCV camping would provide long-term benefits. Those looking for a vehicle free experience at the Seashore would experience long-term benefits as alternative E provides for designated year-round VFAs, as well as seasonal ORV closures in areas such as village beaches and some of the SMAs. Since night driving would be seasonally restricted, but allowed until 10:00 p.m., under alternative E, there would be long-term moderate adverse impacts to night skies due to the hours of night driving allowed, implementation of park-and-stay opportunities, with long-term beneficial impacts during times of seasonal night-driving restrictions.</p> <p><b>Cumulative Impacts:</b>                      Cumulative impacts would be long-term moderate to major adverse to ORV users, and long-term beneficial for visitors who desire a vehicle free beach experience.</p>	<p><b>Impacts of the Alternative:</b>                      Those looking for an experience at the Seashore that includes ORV use would have long-term moderate adverse impacts as the designation of VFAs and carrying capacity limits could or would preclude ORV use, either seasonally or year-round, from some areas of the Seashore that are popular visitor use areas. Improved access would be provided to the soundside under this alternative as well. Those looking for a vehicle-free beach experience at the Seashore would experience long-term benefits as alternative F provides for year-round VFAs, as well as seasonal ORV closures in areas such as village beaches, two new pedestrian trails, 14 new or improved parking areas with pedestrian access, and pedestrian access seaward of prenesting closures (prior to observed breeding activity). Since night driving would be seasonally restricted under alternative F, there would be long-term negligible to minor adverse impacts to night skies, with long-term beneficial impacts year-round in VFAs and seasonally on ORV routes during times of seasonal night-driving restrictions.</p> <p><b>Cumulative Impacts:</b>                      Cumulative impacts would be long-term moderate to major and adverse to ORV users, and long-term beneficial for visitors who desire a vehicle free beach experience.</p>

Table 13. Environmental Impact Summary by Alternative

Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<p><b>Socioeconomic Impacts</b></p>	<p><b>Impact of the Alternative to the Region of Influence:</b> The region of influence (ROI) is expected to experience long-term negligible adverse impacts or long-term beneficial impacts depending on the extent of beach closures. The Seashore villages (the villages bordering the Seashore) would experience the majority of the impacts with the potential for larger short-term impacts to specific businesses that cater most directly to ORV users.</p> <p><b>Impact of the Alternative to Small Business:</b> Small businesses may experience long-term negligible to minor adverse impacts or long-term beneficial impacts depending on the extent of beach closures. Based on visitation statistics in 2007, there is a greater likelihood of negligible impacts.</p> <p><b>Impacts of the Alternative to Preservation Values:</b> As a result of the long-term minor to major impacts to protected species, impacts to preservation values would be long-term moderate adverse.</p>	<p><b>Impact of the Alternative to the Region of Influence:</b> The ROI is expected to experience long-term negligible to minor adverse impacts depending on the extent of beach closures. The Seashore villages would experience the majority of the impacts with the potential for larger short-term impacts to specific businesses that cater most directly to ORV users. Based on the current visitation statistics, the probability of negligible impacts is greater than the probability of minor adverse impacts.</p> <p><b>Impact of the Alternative to Small Business:</b> Small businesses may experience long-term negligible to moderate adverse impacts depending on the extent of beach closures. Based on current visitation statistics there is a greater likelihood of negligible or minor impacts.</p> <p><b>Impacts of the Alternative to Preservation Values:</b> As a result of the long-term minor to moderate impacts to protected species, and addition of protection from seasonal night-driving restrictions, impacts to preservation values would be long-term minor to moderate adverse.</p>	<p><b>Impact of the Alternative to the Region of Influence:</b> The ROI is expected to experience long-term negligible to minor adverse impacts. The Seashore villages would experience the majority of the impacts with the potential for larger short-term impacts to specific businesses that cater most directly to ORV users. Efforts to improve access through pedestrian corridors, when compared to the no-action alternatives, and changes to access ramps would decrease the impacts on businesses that rely on visitors using the beaches affected by the new corridors and ramps relative to the no-action alternatives. However, the longer ORV closures in the fall months may reduce visitation under alternative C relative to the no-action alternatives and make the mid to high impact scenarios more likely.</p> <p><b>Impact of the Alternative to Small Business:</b> Small businesses may experience long-term negligible to moderate adverse impacts, with a greater likelihood of adverse impacts relative to the no-action alternatives due to increased fall ORV closures.</p> <p><b>Impacts of the Alternative to Preservation Values:</b> Adverse impacts to preservation values would be less under alternative C, relative to alternatives A and B, and overall impacts to preservation values would be long-term minor adverse with long-term beneficial impacts from the measures taken to protect sensitive species at the Seashore.</p>	<p><b>Impact of the Alternative to the Region of Influence:</b> The ROI is expected to experience long-term minor adverse impacts. The Seashore villages would experience the majority of the impacts with the potential for larger short-term impacts to specific businesses that cater most directly to ORV users. Compared to the other alternatives, alternative D provides the least access to the beach by ORVs resulting in larger projected adverse impacts.</p> <p><b>Impact of the Alternative to Small Business:</b> Small businesses may experience long-term moderate to major adverse impacts. The adverse impacts are projected to be larger relative to the other alternatives because of the limits on beach access for ORVs.</p> <p><b>Impacts of the Alternative to Preservation Values:</b> Adverse impacts to preservation values would be less under alternative D, relative to alternatives A and B, and the overall impact to preservation values would be long-term minor adverse, with the closure of sensitive areas to ORVs under alternative D year-round substantially increasing the probability of long-term beneficial impacts relative to all other alternatives.</p>	<p><b>Impact of the Alternative to the Region of Influence:</b> The ROI is expected to experience long-term negligible to minor adverse impacts. Based on the visitation statistics for 2008, the probability of negligible impacts is greater than the probability of minor adverse impacts. The Seashore villages would experience the majority of the impacts. Like alternative B, alternative E provides for more ORV access and the impacts would likely be on the lower end of the range compared to alternatives C and D.</p> <p><b>Impact of the Alternative to Small Business:</b> Small businesses may experience long-term negligible to moderate adverse impacts, with a likelihood of adverse impacts in the lower end of the range relative to alternatives C and D due to increased ORV access. closures.</p> <p><b>Impacts of the Alternative to Preservation Values:</b> Adverse impacts to preservation values would be less under alternative E, relative to alternatives A and B, and overall preservation values would be long-term minor to moderate adverse with long-term beneficial impacts from the measures taken by the Seashore to protect threatened and endangered, as well as special status species.</p>	<p><b>Impact of the Alternative to the Region of Influence:</b> The ROI is expected to experience long-term negligible to minor adverse impacts. The Seashore villages would experience the majority of the impacts with the potential for larger short-term impacts to specific businesses that cater most directly to ORV users. Alternative F provides less ORV access to the beach compared to the no-action alternatives, especially with 26 miles of the Seashore designated as year-round VFA. However, some popular areas, such as Cape Point, South Point and Bodie Island spit, would have designated year-round or seasonal ORV routes, subject to resource closures. There are more VFAs for pedestrians because of the ORV route designations, as well as increased parking for pedestrian access. Compared to the no-action alternatives, these measures could increase overall visitation and increase the probability that revenue impacts would be at the low end of the estimated range rather than the high end.</p> <p><b>Impact of the Alternative to Small Business:</b> Small businesses would experience long-term negligible to moderate adverse impacts. The extra efforts to increase ORV access and pedestrian access should increase the probability that the impacts are on the low rather than high end of the range.</p> <p><b>Impacts of the Alternative to Preservation Values:</b> Adverse impacts to preservation values would be less under alternative F, relative to alternatives A and B, and overall preservation values would be long-term minor to moderate adverse, with long-term beneficial impacts from the measures taken by the Seashore to protect threatened and endangered, as well as special status species.</p>

Impact Topic	Alternative A: No Action—Continuation of Management under the Interim Strategy	Alternative B: No Action—Continuation of Management under Consent Decree	Alternative C: Seasonal Management	Alternative D: Increased Predictability and Simplified Management	Alternative E: Variable Access and Maximum Management	Alternative F: NPS Preferred Alternative
<b>Socioeconomic Impacts (continued)</b>	<p><b>Cumulative Impacts:</b> Cumulative Impacts for socioeconomics to the ROI would be long-term negligible to minor adverse or beneficial, depending on national economic conditions.</p>	<p><b>Cumulative Impacts:</b> Cumulative Impacts for socioeconomics to the ROI would be long-term negligible to minor adverse or beneficial, depending on national economic conditions.</p>	<p><b>Cumulative Impacts:</b> Cumulative Impacts for socioeconomics to the ROI would be long-term negligible to minor adverse or beneficial, depending on national economic conditions.</p>	<p><b>Cumulative Impacts:</b> Cumulative Impacts for socioeconomics to the ROI would be long-term negligible to minor adverse or beneficial, depending on national economic conditions.</p>	<p><b>Cumulative Impacts:</b> Cumulative Impacts for socioeconomics to the ROI would be long-term negligible to minor adverse or beneficial, depending on national economic conditions.</p>	<p><b>Cumulative Impacts:</b> Cumulative Impacts for socioeconomics to the ROI would be long-term negligible to minor adverse or beneficial, depending on national economic conditions.</p>
<b>Seashore Operations and Management</b>	<p><b>Impacts of the Alternative:</b> Overall, each division could accomplish within current funding, without shifting priorities or having a noticeable change in operations, resulting in long-term negligible adverse impacts to all areas of Seashore operations.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to Seashore Operations and Management would be long-term negligible adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, there would be an increase in duties related to ORV management for staff in the park management/administration, visitor protection, and resources management divisions. Although these staff could accomplish these duties within existing budgets, it would require them to re-prioritize and re-allocate staff, and would not leave staff with adequate time to address other needs at the park outside of ORV management, resulting in long-term moderate adverse impacts. Staff in facility management and Interpretation would not see a large change in operations and would be able to accomplish ORV related tasks within current funding, without shifting priorities or having a noticeable change in operations, resulting in long-term negligible adverse impacts to these two divisions. Overall, impacts to Seashore operations would be long-term moderate adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to Seashore Operations and Management would be long-term negligible to minor adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, there would be an increase in duties related to ORV management for staff in the park management/administration, resources management, facility management divisions that could result in some re-prioritization of work, but would not be expected to impact overall duties resulting in long-term minor adverse impacts. In the visitor protection division, staff could accomplish their duties with existing budgets, but it would require them to re-prioritize and re-allocate staff, and would not leave staff with adequate time to address other needs at the park outside of ORV management, resulting in long-term moderate adverse impacts. Staff in the interpretation division would not see a large change in operations and would be able to accomplish ORV related tasks within current funding, without shifting priorities or having a noticeable change in operations, resulting in long-term negligible adverse impacts Overall, impacts to Seashore operations would be long-term, minor to moderate (but mostly minor) adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to Seashore Operations and Management would be long-term, minor to moderate, adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, there would long-term negligible adverse impacts to all divisions as each division would be expected to execute their duties from existing, or expected, funding sources, without having to re-prioritize staff. These impacts are due, in part, to the expected cost recovery under the proposed permit program. Overall impacts to Seashore operations would be long-term negligible adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to Seashore Operations and Management would be long-term negligible adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, there would be an increase in duties related to ORV management for staff in the facility management division that could result in some re-prioritization of work, but would not be expected to impact overall duties resulting in long-term minor adverse impacts. In the park management/administration division, the increase in ORV related responsibilities would be similar, but slightly greater with long-term minor to moderate adverse impacts. In the visitor protection and resources management divisions, staff could accomplish their duties with existing budgets, but it would require them to re-prioritize and re-allocate staff, and would not leave staff with adequate time to address other needs at the park outside of ORV management, resulting in long-term moderate adverse impacts. Staff in the Interpretation division would not see a large change in operations and would be able to accomplish ORV related tasks within current funding, without shifting priorities or having a noticeable change in operations, resulting in long-term negligible adverse impacts. Overall impacts to Seashore operations would be long-term moderate adverse.</p> <p><b>Cumulative Impacts:</b> Cumulative impacts to Seashore Operations and Management would be long-term minor to moderate adverse.</p>	<p><b>Impacts of the Alternative:</b> Overall, there would be an increase in duties related to ORV management for staff in the facility management and park management/administration divisions that could result in some re-prioritization of work, but would not be expected to impact overall duties resulting in long-term minor adverse impacts. In the visitor protection and resources management divisions, staff could accomplish their duties with existing budgets, but it would require them to re-prioritize and re-allocate staff, and would not leave staff with adequate time to address other needs at the park outside of ORV management, resulting in long-term moderate adverse impacts. ## CHAPTER 3: AFFECTED ENVIRONMENT

The “Affected Environment” describes existing conditions for those elements of the natural and cultural environments that would be affected by the implementation of the actions considered in this plan/EIS. The natural environment components addressed include wetlands and floodplains; federally listed threatened or endangered species; state-listed and special status species; wildlife and wildlife habitats (with a focus on birds and invertebrate species that could be affected by ORV use or management); soundscapes; visitor use and experience (including night skies); socioeconomic resources; and Seashore management and operations. Impacts for each of these topics are analyzed in “Chapter 4: Environmental Consequences.”

### WETLANDS AND FLOODPLAINS

#### WETLANDS

Wetlands include areas inundated or saturated by surface or groundwater for a sufficient length of time during the growing season to develop and support characteristic soils and vegetation. The NPS classifies wetlands based on the USFWS Classification of Wetlands and Deepwater Habitats of the United States (the Cowardin classification system). Based on this classification system, a wetland must have one or more of the following attributes:

- The habitat at least periodically supports predominantly hydrophytic (wetland) vegetation.
- The substrate is predominantly undrained hydric soil.
- The substrate is nonsoil and saturated with water, or is covered by shallow water at some time during the growing season (Cowardin et al. 1979).

The majority of the undeveloped acreage within the Seashore can be classified as a wetland. The predominant wetland types at the Seashore are marine and estuarine. Marine wetlands occur along the beaches on the oceanside of the Seashore, and estuarine wetlands generally occur along the soundside, adjacent to the many tidal creeks that are prevalent along the islands. Non-wetland or “upland” areas of the Seashore include areas landward of the dune line, areas around NC-12, and other developed areas such as those in and around villages and Seashore facilities.

Marine wetlands at the Seashore are located in the intertidal zone (from extreme high tide to extreme low tide) and in the subtidal zone, which includes areas permanently submerged below coastal waters (Cowardin et al. 1979). Generally, areas of the Seashore’s beaches between the toe of the dune and the extreme low tide water line are considered intertidal marine wetlands. Marine wetlands are found along the entire length of the ocean shoreline and are typical of a sandy beach environment, subject to high wind and wave energy. Estuarine wetlands consist of deepwater and adjacent tidal wetland areas that are often partially enclosed by land but are influenced by marine waters and freshwater runoff from adjacent uplands (Cowardin et al. 1979). Estuarine wetlands at the Seashore typically fall into two classes: emergent or scrub–shrub. Emergent wetlands, also referred to as tidal marshes, are characterized by herbaceous perennial vegetation such as saltmarsh cordgrass (*Spartina alterniflora*), black needlerush (*Juncus roemerianus*), bulrush (*Scirpus* spp.), and cattail (*Typha* spp.) (NCDENR 2008a). Scrub–shrub wetlands are typically dominated by woody vegetation less than 20 feet tall. Typical vegetation species found in these wetlands include wax myrtle (*Myrica cerifera*) and eastern red cedar (*Juniperus virginiana*) (Sutter 1999). Although most wetlands at the Seashore are tidal, there are also some areas of nontidal wetlands, located primarily on Hatteras Island near the village of Buxton and Buxton Woods

Coastal Reserve. These wetland areas include forested and emergent wetlands and are predominantly freshwater swamps and marshes that are not influenced by the tides.

Wetland areas provide substantial environmental and economic benefits to the Seashore and surrounding areas of coastal North Carolina. For example, wetlands trap sediment and pollutants from stormwater runoff and provide a natural filter before this runoff can enter local waterways. Wetlands also store large volumes of water and function like sponges to reduce the likelihood of flooding during storm events. Wetlands also protect the shoreline from erosion and provide excellent habitat for fish and wildlife species, many of which are threatened or endangered (NCDENR 2008b).

## **FLOODPLAINS**

North Carolina's barrier islands have historically been and continue to be affected by coastal forces and flooding events. The barrier islands that comprise the Seashore are flat and narrow and lie adjacent to the shallow and wide Pamlico Sound. The widest part of the Seashore islands is near Cape Point, between Buxton and Frisco (Pendleton et al. 2005). According to Federal Emergency Management Agency (FEMA) Flood Insurance Rate Maps, most of the Seashore is within the 100-year floodplain, with the exception of some areas within the 500-year floodplain (Shaded X Zone) located at the Navy tower site on Bodie Island and a larger area near Buxton.

Generally, lands along the ocean beaches and adjacent to the sound (at wide points) are in flood zone "VE," which is the flood insurance rate zone that corresponds to 100-year coastal floodplains that have additional hazards associated with storm waves. Zone "VE" is also referred to as the "Coastal High Hazard Area." The remainder of the Seashore that is located within the 100-year floodplain and not directly adjacent to the ocean or sound lies within the "AE" zone, which is subject to waves less than 3 feet high (NCDCCPS 2008).

Because the Seashore is almost entirely within the 100-year floodplain and is subject to high water table conditions and high wave action, many areas are subject to drainage and flooding problems that often result from storm events. Areas near Buxton Woods and Cape Point Campground have been documented as historically flood-prone and are examples of popular Seashore destinations that experience flooding during times of above-average precipitation events (Martin pers. comm. 2003).

## **FEDERALLY LISTED THREATENED OR ENDANGERED SPECIES**

This section addresses species present at the Seashore that are listed by the USFWS as either endangered or threatened. In some cases, the species may also be listed by the State of North Carolina. These species include the federally and state-listed piping plover (*Charadrius melodus*); federally and state-listed loggerhead (*Caretta caretta*), green (*Chelonia mydas*), and leatherback (*Dermochelys coriacea*) sea turtles; and federally and state-listed seabeach amaranth (*Amaranthus pumilus*).

Species listed only by the state, and not federally listed as threatened and endangered, are discussed in the "State-Listed and Special Status Species" section of this chapter.

### **PIPING PLOVER**

The piping plover is a small (6 to 7 inches long, weighing 1.5 to 2.2 ounces), highly camouflaged, sand-colored shorebird endemic to North America. The USFWS recognizes three distinct piping plover population segments: (1) the Atlantic Coast (from the Maritime Provinces of Canada to the Outer Banks of North Carolina); (2) the Great Lakes (along Lake Superior and Lake Michigan); and (3) the Great Plains (from southern, prairie Canada to Nebraska).

Wintering populations are found on the Atlantic Coast from North Carolina to Florida, on the Gulf Coast from Florida to Mexico, and in the Caribbean, with the greatest number of wintering birds found in Texas. Fewer than 3,000 breeding pairs of piping plovers were detected in the United States and Canada in 2001, although the most recent breeding census estimated breeding pairs in excess of 3,500 (Elliott-Smith et al. 2009). Piping plovers were common along the Atlantic Coast during much of the 19th century, but nearly disappeared due to excessive hunting for decorative feathers. Following passage of the MBTA in 1918, plover numbers recovered to a 20th century peak in the 1940s. Increased development and beach recreation after World War II caused a population decline that led to federal protection for the plover (USFWS 2007b). Habitat loss caused by human development and recreation, and low reproductive rates caused by disturbance and predation, were considered to be the primary causes of the decline (Elliot-Smith and Haig 2004). The Atlantic Coast population was federally listed in 1986 as threatened (FR 1985). At the time of listing, there were approximately 790 Atlantic Coast pairs, and the species was in decline. Therefore, a recovery target of 2,000 pairs was established in the 1996 Revised Recovery Plan for the Atlantic Coast population (USFWS 1996a). Disturbance and predation were intensively managed after the listing, and the Atlantic Coast population rose to 1,890 pairs by 2007 (USFWS 2007c), but was still short of the recovery goal of 2,000 pairs (USFWS 1996a; Hecht pers. comm. 2008; USFWS 2009a).

**Piping Plover**

Credit: Gene Neiminen / USFWS

The population for the Atlantic Coast Southern Region (or Recovery Unit), which comprises the states of Delaware, Maryland, Virginia, and North Carolina, was estimated at 333 pairs in 2007, which was the highest since 1986, but still short of the regional goal of 400 pairs (table 14). North Carolina experienced more than a 50% decline in breeding pairs from 1989 (55 pairs) to 2004 (20 pairs) (USFWS 2004a) for reasons discussed in the “Risk Factors” section later in this chapter; however, the number of breeding pairs was estimated at 64 pairs in 2008, which represents the highest number recorded in North Carolina in the years that complete surveys have been conducted (1989–2008) (NCWRC 2008a). For the 2009 season there were a total of 54 pairs in the state (USFWS 2009b); in 2010, there were an estimated 51 pairs in the state (Schweitzer pers. comm. 2010).

### **Piping Plover in North Carolina**

North Carolina is currently the only state on the Atlantic Coast that hosts piping plovers during all phases of their annual cycle, including the establishment and holding of territories, courtship and copulation, nest scraping and nest building, egg laying and incubation, chick rearing and fledging, and migration and wintering (Cohen et al. 2010). Plovers from the endangered Great Lakes population have been observed in fall and spring migration and during the wintering period (Cohen et al. 2008). Early nesting records indicate that plovers were nesting at Pea Island in 1901 and 1902 (Golder 1986). The first published account of breeding piping plovers in North Carolina is from 1960, when a young bird was photographed in early June on Ocracoke Island (Golder 1985).

— = No data available.

At the Seashore, four nests and one brood were observed in 1984, and five chicks were confirmed to have fledged that year. All four nests were located adjacent to least tern (*Sterna antillarum*) colonies on wide, open, sandy flats (Golder 1985). Nine pairs were counted in 1985 (Golder 1986), and 10 pairs in the summer of 1987 (Cooper 1990). The piping plover population reached a high of 15 pairs at the Seashore in 1989, and subsequently varied between 11 and 14 pairs through 1996, after which a sharp decline began (see figure 3). The population at the Seashore reached a low of two breeding pairs in 2002 and 2003, with only three breeding pairs reported in 2004 and 2005 (NPS 2009b). The population increased to 6 pairs in 2006 and 2007 and to 11 pairs by 2008 (NPS 2009b). The Seashore recorded nine piping plover breeding pairs during the 2009 season and 12 breeding pairs in the 2010 season (Muiznieks pers. comm. 2009; Muiznieks pers. comm. 2010a).

Source: NPS 2009b; Muiznieks pers. comm. 2009; Muiznieks pers. comm. 2010a

**FIGURE 3. NUMBERS OF PIPING PLOVER BREEDING PAIRS, CAPE HATTERAS NATIONAL SEASHORE, 1987–2010**

NCWRC staff conducted a piping plover breeding census along the coast of North Carolina during the June 1 through June 9, 2008, census window. The census included all suitable habitat on ocean and inlet beaches with the exception of Browns Island, which lies within a military live-fire training range. Sixty pairs and seven individual birds were counted during the census window. The end-of-season best estimate, which includes pairs discovered after the census window, was 64 pairs and 5 individuals, which was a 5% increase from the 2007 estimate of 61 pairs and is the highest number recorded in North Carolina in the years that complete surveys have been conducted (1986–2008; see figure 4). However, the end of season estimates indicated a total of 54 breeding pairs in the state in 2009 and 51 in 2010 (USFWS 2009b; Schweitzer pers. comm. 2010). Statewide, the distribution of piping plovers in 2008 was similar to previous years, with the majority of nesting pairs found at Cape Lookout National Seashore (NCWRC 2008a).

Source: USFWS 2004a, 2004b, 2005a, 2006b, 2007c, 2008c; USFWS 2009b; Schweitzer pers. comm. 2010  
Data reflect total season estimates, which includes birds found after the census window had closed

**FIGURE 4. NUMBERS OF PIPING PLOVER BREEDING PAIRS IN NORTH CAROLINA, 1986–2010**

### Habitat Description

On the Atlantic Coast, piping plovers nest in sand, gravel, or cobble substrates in backshore, dune, interdune blowout, overwash fan, and barrier flat zones of open or sparsely vegetated beaches. Nest sites may have little or no slope (Cairns 1982; Burger 1987), although nesting does occur on lower-elevation dunes (Cairns 1982). On wide beaches, piping plovers nest in the open to maintain a wide field of view, but on narrower beaches nests can be established under clumps of vegetation (Cairns 1982; USFWS 1996a). Where beaches are wide, piping plovers tend to nest far from the tide line to reduce risk of nest overwash, but this can place nests closer to vegetated dunes where the risk of predation is higher (Burger 1987). Piping plovers have also been observed nesting within least tern colonies, which could provide an added defense against predators due to the antipredator behavior of least terns (Burger 1987).

**Plover Habitat**

Credit: NPS

In the winter and on migration, piping plovers tend to be found in areas with wide beaches and inlet habitats, foraging in moist, substrate habitat that includes both low- and high-wave-energy intertidal zones, mudflats, moist sand flats, ephemeral pools, shores, and brackish ponds (Cohen et al. 2010; Elliot-

Smith and Haig 2004; Nicholls and Baldassarre 1990; Wilkinson and Spinks 1994; USFWS 2009a). During winter distribution surveys on the Atlantic Coast from 1986 to 1987, piping plovers were almost always found associated with other species of shorebirds, such as sanderlings (*Calidris alba*), least sandpipers (*C. minutilla*), or western sandpipers (*C. mauri*), in addition to other piping plovers (Nicholls and Baldassarre 1990).

### Critical Habitat Designation

All piping plover breeding sites at the Seashore were designated as critical habitat for wintering birds, as defined by the federal ESA (FR 2001) until 2004, when a court decision vacated the designation for Oregon Inlet, Cape Point, Hatteras Inlet, and Ocracoke Island (*Cape Hatteras National Seashore Access Preservation Alliance versus U.S. Dept. of the Interior*, 344 F. Supp. 2d 108 [D.D.C. 2004]). A rule to revise designated critical habitat for the wintering population of the piping plover in North Carolina was proposed in 2006 (Federal Register (FR) notice 71 FR 33703). That proposed rule described four coastal areas (named Units NC-1, NC-2, NC-4, and NC-5), totaling approximately 739 hectares (1,827 acres) entirely within the Seashore, as critical habitat for the wintering population of the piping plover. The USFWS also proposed to add 87 hectares (215 acres) of critical habitat to two previously proposed units. As a result, the proposed revised critical habitat designation for the species now includes four revised critical habitat units totaling approximately 826 hectares (2,042 acres). The final rule for the revised critical habitat designation became effective on November 20, 2008 (73 FR 62816). On February 6, 2009, Cape Hatteras Access Preservation Alliance and Dare and Hyde Counties, North Carolina, filed a legal challenge to the revised designation. On August 18, 2010, a U.S. District Court granted the government's motion for summary judgment and dismissed the case with prejudice, and the critical habitat designation for these four units remains in effect.

**Piping Plover Nest Site**

Credit: NPS

Critical habitat identifies specific areas that are essential to the conservation of a listed species, or that contain physical and biological features that are essential to the species and that may require special management considerations or protection. Approximately 2,043 acres in Dare and Hyde counties are designated as critical habitat for the wintering population of the piping plover (73 FR 62816).

Section 7 of the ESA requires federal agencies to ensure that actions they authorize, fund, or carry out are not likely to destroy or adversely modify designated critical habitat. Activities that may destroy or adversely modify critical habitat include those that alter the primary constituent elements (PCEs) to an extent that the value of critical habitat for both the survival and recovery of the species is appreciably reduced (65 FR 41793).

The PCEs for the wintering population of the piping plover are the habitat components that support foraging, roosting, and sheltering and the physical features necessary for maintaining the natural processes that support these habitat components. Specifically, the PCEs are

- (1) Intertidal sand beaches (including sand flats) or mud flats (between the mean lower low water line and annual high tide) with no or very sparse emergent vegetation for feeding. In some cases, these flats may be covered or partially covered by a mat of blue-green algae.
- (2) Unvegetated or sparsely vegetated sand, mud, or algal flats above annual high tide for roosting. Such sites may have debris or detritus and may have micro-topographic relief (less than 20

inches (50 centimeters) above substrate surface) offering refuge from high winds and cold weather.

- (3) Surf-cast algae for feeding.
- (4) Sparsely vegetated backbeach, which is the beach area above mean high tide seaward of the dune line, or in cases where no dunes exist, seaward of a delineating feature such as a vegetation line, structure, or road. Backbeach is used by plovers for roosting and refuge during storms.
- (5) Spits, especially sand, running into water for foraging and roosting.
- (6) Salterns, or bare sand flats in the center of mangrove ecosystems that are found above mean high water and are only irregularly flushed with sea water.
- (7) Unvegetated washover areas with little or no topographic relief for feeding and roosting. Washover areas are formed and maintained by the action of hurricanes, storm surges, or other extreme wave actions.
- (8) Natural conditions of sparse vegetation and little or no topographic relief mimicked in artificial habitat types (e.g., dredge spoil sites).

Critical habitat does not include manmade structures (such as buildings, aqueducts, runways, roads, and other paved areas) and the land on which they are located existing within the legal boundaries as of November 20, 2008 (50 CR 17.95 b (1)(2)).

Of the 2,043 acres of designated critical habitat in Dare and Hyde counties, approximately 1,827 acres are located within the boundaries of the Seashore and are located at Bodie Island Spit, Cape Point, Hatteras Inlet Spit, Ocracoke Inlet Spit, and South Point (73 FR 62816).

The four units of designated critical habitat that include acreage within the Seashore are described below:

NC-1: This unit extends from the southern portion of Bodie Island through Oregon Inlet to the northern portion of Pea Island. It begins at ramp 4 near the Oregon Inlet Fishing Center on Bodie Island and extends approximately 7.6 kilometers (4.7 miles) south to the intersection of NC-12 and Salt Flats Wildlife Trail on Pea Island. The unit is bounded by the Atlantic Ocean on the east and Pamlico Sound on the west and includes lands from the MLLW (mean lower low water) on the Atlantic Ocean shoreline to the line of stable, densely vegetated dune habitat (which is not used by piping plovers and where PCEs do not occur) and from the MLLW on the Pamlico Sound side to the line of stable, densely vegetated habitat, or (where a line of stable, densely vegetated dune habitat does not exist) lands from MLLW on the Atlantic Ocean shoreline to the MLLW on the Pamlico Sound side. Any emergent sandbars south and west of Oregon Inlet, including Green Island and lands owned by the State of North Carolina are included.

NC-2: This unit is entirely within the Seashore and encompasses Cape Point. The unit extends south approximately 4.5 kilometers (2.8 miles) from the ocean groin near the old location of the Cape Hatteras Lighthouse to the point of Cape Hatteras, and then extends west 7.6 km (4.7 miles) along South Beach to the edge of ramp 49 near the Frisco Campground. The unit includes lands from the MLLW on the Atlantic Ocean to the line of stable, densely vegetated dune habitat (which is not used by the piping plover and where PCEs do not occur).

NC-4: This unit extends from the western end of Hatteras Island to the eastern end of Ocracoke Island. The unit extends approximately 7.6 kilometers (4.7 miles) southwest from the first beach access point at the edge of ramp 55 at the end of NC-12 near the Graveyard of the Atlantic Museum on the western end of Hatteras Island to the edge of the beach access at the oceanside parking lot (approximately 0.1 mile south of ramp 59) on NC-12, approximately 1.25 kilometers (0.78 miles) southwest of the ferry terminal on the northeastern end of Ocracoke Island. The unit includes lands from the MLLW on the Atlantic Ocean shoreline to the line of stable, densely vegetated dune habitat (which is not used by the piping plover and where PCEs do not occur) and from the MLLW on the Pamlico Sound side to the line of stable, densely vegetated habitat, or (where a line of stable, densely vegetated dune habitat does not exist) lands from MLLW on the Atlantic Ocean shoreline to the MLLW on the Pamlico Sound side. All emergent sandbars within Hatteras Inlet between Hatteras Island and Ocracoke Island, including lands owned by the State of North Carolina are included.

NC-5: This unit is entirely within the Seashore and includes the western portion of Ocracoke Island beginning at the beach access point at the edge of ramp 72, extending west approximately 3.4 kilometers (2.1 miles) to South Point and then back east on the Pamlico Sound side to a point where stable, densely-vegetated dune habitat meets the water. This unit includes lands from the MLLW on the Atlantic Ocean shoreline to the line of stable, densely-vegetated dune habitat (which is not used by the piping plover and where PCEs do not occur) and from the MLLW on the Pamlico Sound side to the line of stable, densely vegetated habitat, or (where a line of stable, densely vegetated dune habitat does not exist) lands from MLLW on the Atlantic Ocean shoreline to the MLLW on the Pamlico Sound side. All emergent sandbars within Ocracoke Inlet are also included.

## Diet

Piping plovers feed primarily on freshwater, marine, terrestrial, and benthic invertebrates (Elliot-Smith and Haig 2004) such as marine worms, fly larvae, beetles, crustaceans, or mollusks (USFWS 1996a, 2009a). Adults forage both day and night (Staine and Burger 1994), but young chicks are brooded during the night and therefore feed by day (Wolcott and Wolcott 1999). During territory establishment, foraging adults exhibit a preference for a moist substrate habitat that particularly includes mudflats, sand flats, ephemeral pools, and shores of brackish ponds and excludes the high-wave-energy intertidal zone (Cohen et al. 2010). Broods forage primarily on damp sand flats or moist substrate habitat, where the abundance of prey is much higher than in other habitats (Kuklinski et al. 1996).

**Piping Plovers Foraging along Shoreline**

Credit: Gene Nieminen / USFWS

Chicks with access to moist substrate habitat survived better than chicks without such access in Virginia (Loefering and Fraser 1995) and Rhode Island (Goldin and Regosin 1998). A study in New York in 1992 and 1993 found that piping plover broods had higher foraging rates in areas with ephemeral pools and tidal flats, which suggested that these habitats were superior. This study also documented higher incidences of arthropods in the moist substrate habitat, which could explain the increased plover numbers and survival rates in these habitat types. Management implications of this study include conserving a variety of foraging habitat (Elias et al. 2000). Burger (1994) found that when broods had access to a diversity of foraging habitat zones, the impact of human disturbance was reduced because chicks had opportunities to escape disturbances and still forage.

## Breeding Biology

On the Atlantic Coast, breeding territory establishment and courtship generally begin in late March, the first nests are initiated in late April, and the brood-rearing period extends from late May to mid-August (Cohen 2005). On beaches with more birds in the northern end of the Atlantic Coast breeding range, most pairs establish breeding territory within a day or two of the birds' arrival in early spring, whereas pairs on sites with fewer birds can take several days or weeks longer to become established (Elliot-Smith and Haig 2004).

Piping plovers are primarily monogamous during the breeding season but often change mates between seasons. The nest is built by the male and consists of a shallow scrape in sandy substrate that may or may not be lined with pebbles and shell fragments.

The normal clutch size is four (USFWS 2007b, 2009a), and the average duration for egg laying is six days (Elliot-Smith and Haig 2004). Replacement of lost or destroyed eggs has not been reported. If one or more eggs are lost, the pair continues to incubate the remaining eggs. Incubation is shared by males and females and typically commences the day of clutch completion, but sometimes occurs when the next-to-last egg is laid (Elliott-Smith and Haig 2004).

The length of incubation ranges from 25 to 29 days, and a pair will re-nest multiple times if successive clutches are destroyed, but re-nesting after the chicks hatch is rare (Elliott-Smith and Haig 2004). Chicks leave the nest scrape within a few hours of hatching, except when a nest hatches

at night, and they never return (Wolcott and Wolcott 1999). Broods may move hundreds of meters away from the nest site during the first week after hatching (USFWS 1996a, 2009a). Chicks are vulnerable soon after hatching, and survival rates are lower if the brood is forced to move. Members of a breeding pair share brood-rearing duties, though some females desert broods within 5 to 17 days (Elliott-Smith and Haig 2004). Although chicks follow adults to a foraging habitat, chicks forage for themselves. Fledging time ranges from 25 to 35 days (USFWS 1996a, 2009a), and most adults and young depart the breeding grounds between mid-July and early September (Cohen et al. 2010).

## Breeding Chronology and Performance at Cape Hatteras National Seashore

Locally breeding piping plovers arrive at the Seashore in mid-March, begin courting and pairing in April, and begin to scrape and/or build nests by the third week of April. Bodie Island Spit, Cape Point, South Beach, Hatteras Inlet Spit, North Ocracoke Spit, and South Point Ocracoke (South Point) all contain potential nesting habitat. As of 2010, nesting has been documented in all of these areas within the last 10 years. Although breeding pairs or nests had not been identified on the north end of Ocracoke Island since 1996, resource management staff members continued monitoring this area for potential plover activity and identified one breeding pair and one nest in 2010. Under the Interim Strategy, Seashore personnel would generally begin monitoring for piping plover arrival and prenesting behavior in late March and early April. Monitoring and surveys of these sites were conducted a minimum of three times per week. However, the 2008 consent decree required staff to begin monitoring these sites on March 15, and monitor every two days from March 15 to April 15, and daily from April 16 to July 15. Bodie Island Spit had to be monitored daily from March 15 to July 15. All known nests are protected by predator exclosures, which have been in use at the Seashore since 1994. Once nests are located, they are briefly approached once a week to inspect the exclosure, count eggs, and search for predator tracks. Morning and evening observations begin when clutches are expected to hatch. Monitors observe from a distance for

evidence of hatching or chicks. After hatching, in areas not open to ORV use, the broods are monitored a few hours in the morning and a few hours in the afternoon until the chicks have fledged or are lost. Seashore personnel document brood status, behavior, individual bird and/or brood movements, human disturbance, predator interactions, and other significant environmental events.

Table 15 shows the numbers of breeding pairs of piping plovers at the six known nesting sites from 1987 to 2010. Table 16 provides data on piping plover hatching and fledging success at the Seashore from 1992 through 2010. The 11 breeding pairs identified in 2008 marks an 83% increase from the 6 pairs identified in 2007, and the 12 breeding pairs identified in 2010 marks a 100% increase from the 2007 total (NCWRC 2008a; Muiznieks pers. comm. 2010a). In 2010, 15 piping plover chicks successfully fledged, which represents the greatest number of fledged plover chicks ever documented at the Seashore.

Source: NPS 2009b; NPS 2010d; Muiznieks pers. comm. 2010a

<sup>a</sup> Percentage of all known eggs.

<sup>b</sup> Fledge rate is defined as the number of fledged chicks per breeding pair (number of total pairs).

<sup>c</sup> Assumes three eggs from a brood whose nest was not found.

<sup>d</sup> Assumes two eggs from a brood whose nest was not found.

<sup>e</sup> Includes those presumed hatched.

<sup>f</sup> Assumes one egg from a brood whose nest was not found.

<sup>g</sup> Based on consultation with USFWS, it was determined that Nest 1 and Nest 2 were a single nesting attempt.

Fledge rate (or reproductive rate) is defined as the number of chicks that survive until fledging age per breeding pair. Since 1989, reproductive rates at the Seashore have ranged from 0.00 to 2.00 chicks per breeding pair, with an average rate over the 19 years from 1992 to 2010 of 0.70 chicks per breeding pair (NPS 2009b; Muiznieks pers. comm. 2010a). During 2009, a total of 9 breeding pairs fledged 6 chicks, which is a rate of 0.67 chicks per pair (NPS 2010d). However, a rate of 1.25 fledged chicks per breeding pair annually would be needed to sustain the population (USFWS 1996a), and the recovery goal set by the USFWS is 1.50 fledged chicks per breeding pair. Although a fledge rate of 1.25 chicks per breeding pair was achieved at the Seashore in 2010, the fledge rate at the Seashore has averaged less than half the recovery goal since 1992, but in 2010 was at the level needed to sustain the population.

The decline in the local breeding population (figure 5) from 1995 to 2003 is likely a reflection of the low reproductive rate (NPS 2005a) and resultant lack of recruitment. However, the increase in the numbers of piping plover breeding pairs since 2003 is encouraging.

**FIGURE 5. NUMBERS OF PIPING PLOVER BREEDING PAIRS AND FLEDGED CHICKS AT CAPE HATTERAS NATIONAL SEASHORE, 1992–2010**

### Hatching and Fledging Success at Primary Nesting Sites

The following tables (table 17 through table 22) provide a summary of hatching and fledging success at each of the individual primary breeding sites from the early 1990s through 2010. Average fledge rates<sup>5</sup> across the six breeding sites ranged from 0.13 at Bodie Island Spit to 0.90 at South Beach. In 2010, Cape Point achieved a 2.50 average fledge rate, the only site in 2010 to be above the 1.50 goal set by the 1996 revised recovery plan. In addition, there were eight instances of years when one or more sites did meet or exceed this goal, indicating that despite poor Seashore-wide recruitment, some primary nesting sites performed at or above this expectation in some years.

<sup>5</sup> “Annual fledge rate” is defined as the number of chicks fledged per breeding pair. “Average fledge rate” is the average of the annual fledge rates for years when there was at least one breeding pair.

### Nest Loss/Abandonment

Nest loss and abandonment have had significant impacts on piping plover reproduction at the Seashore. In the 19 seasons from 1992 through 2010, 40% of nests (of 187 discovered) were lost or abandoned (figure 6). Factors contributing to nest loss and abandonment include weather, predation, and human disturbance, which are discussed in detail under the “Risk Factors” section later in this chapter.

### Nonbreeding Population

In addition to supporting a local breeding population, the Seashore also hosts migrating and wintering piping plovers from the threatened Atlantic Coast population and the endangered Great Lakes population). The Outer Banks is an important stopover area for migrating shorebirds along the Atlantic Coast. Fall migrants arrive at the Outer Banks in July, peak in August and September, and depart by November (Dinsmore et al. 1998). The distribution and abundance of nonbreeding populations at the Seashore are less well documented than the local breeding population. Documenting and protecting nonbreeding piping plovers and their habitats are priorities articulated in the recovery plans for all three North American breeding populations (USFWS 1988, 1996a, 2003, 2009a). Recognizing the importance of the Outer Banks to wintering piping plovers, the USFWS designated 2,043 acres of critical habitat in Dare and Hyde counties in November 2008 (FR 2008).

Wintering piping plovers on the Atlantic Coast select wide beaches in the vicinity of inlets that are associated with a high percentage of moist substrate habitat (Nicholls and Baldassarre 1990; Wilkinson and Spinks 1994). Because tidal regimes and fall and winter storm patterns often cause piping plovers to

move among habitat patches, a diversity of habitat patches may be important to wintering populations (Burger 1994; Nicholls and Baldassarre 1990).

Cohen and others (2010) studied nonbreeding piping plovers at the Seashore from 2000 to 2005. The results of this study indicated that the greatest number of nonbreeding piping plovers at the Seashore occurs during the fall migration, which begins in July and peaks between July and September (see table 23). The fall migration counts were highest at South Point, followed by Oregon Inlet (Bodie Island Spit, Pea Island NWR, and, formerly, Green Island, which is now largely unusable for plovers because of vegetation growth), then Hatteras Inlet Spit, and finally Cape Point (Cohen et al. 2010).

NOTE: Not all sites were surveyed during the designated survey days (typically, only one or two sites were surveyed on a given survey day), so the numbers in the table provide only a rough idea of the total size of the nonbreeding population.

During this time, the first banded winter residents appeared in August; however, other wintering birds could have arrived in July. Cohen suggested that the nonbreeding population from December to January probably consisted entirely of winter residents and estimated that although the size of the resident wintering population at the Seashore was not precisely known, it may be on the order of 20 to 35 birds (Cohen et al. 2010). In the winter of 2004–2005, the maximum numbers seen were about 50% of the

recent norm; however, whether this observed difference was because of a difference in survey methodology is unknown. The highest counts of wintering residents were at Bodie Island Spit and South Point. Based on a sample of banded birds, winter residents can be present until April (Cohen et al. 2010). Spring piping plover migrants first appear in February or early March, and their numbers peak in late March or April (table 23). Sites at Bodie Island Spit have had the highest abundance of spring migrants, followed by South Point, with fewer at Hatteras Inlet Spit and Cape Point / South Beach (Cohen et al. 2010).

NPS staff documented nonbreeding piping plovers' use of the Seashore throughout 2006. Migratory birds appeared to peak in August and September, with a high count of 93 birds at South Point on August 10 (table 24). South Point revealed the highest counts during fall migration. Three surveys at South Point were coordinated with Seashore surveys on North Core Banks to investigate bird abundance around Ocracoke Inlet (table 24).

Seashore staff also documented nonbreeding plovers' use of the Seashore beginning at the end of the breeding season in August 2007 through March 2008 and from August 2008 to March 2009 (see figure 7), although surveys were limited to the points and spits. Figure 7 indicates the number of piping plover observations recorded per sampling event (or unit of effort), which is also referred to as "normalized" data, which were used as a means to control a varying level or effort across sampling units. In 2007, migratory birds peaked in September, with a high of 33 counted on September 7, 2007, on South Point (NPS 2009b). After the migrants passed through the area in September 2007, plover numbers appeared to stabilize over the winter months except in February 2008, when there was an unexplained drop in numbers. In 2008, the number of migratory plovers peaked in August and numbers declined in September to a level similar to the previous year. The number of birds at the Seashore continued to decline until February 2009, when the migrants started passing through the Seashore again (figure 7).

Seashore staff documented the habitat type in which migratory and wintering piping plovers were observed from August 2007 to March 2008 and from August 2008 to March 2009 (figure 8). Of the 717 observations, 458 were in mudflat / algal flat, 157 were in sand flat, 67 were in foreshore, and 26 were in wrack line habitat (NPS 2009b; Muiznieks pers. comm. 2009).

In addition to the monitoring conducted by Cohen and others (2010) and Seashore staff, the Southeast Coast Network (SECN) Inventory and Monitoring Program conducted a comprehensive study on wintering shorebirds at the Seashore. Pilot implementation of a long-term shorebird monitoring protocol began in mid-July 2006 and the first report was published in March 2009. The study found that the fall migration appeared to peak in August (figure 9) and the spring migration likely peaked in May, but nest initiation by piping plover and logistical issues precluded consistent sampling later than April in any given year. The three highest single-day counts during the pilot study (for sampled areas only) were 24 in July 2006, 50 in August 2006, and 14 in April 2007. Monthly normalized counts (number of birds observed per 30-minute sampling event) are shown on figure 10.

The SECN study found that the majority of piping plover observations occurred in mudflat / algal flat and foreshore habitat types (figure 11).

**FIGURE 11. NUMBERS OF NONBREEDING PIPING PLOVER (PIPL) OBSERVATIONS BY HABITAT TYPE AND TIDE STAGE AT CAPE HATTERAS NATIONAL SEASHORE, 2006–2007**

The results of the SECN study were consistent with previous studies that found that the moist substrate habitat type is thought to play a vital role in the survival of nonbreeding piping plovers. It was also noted that migratory and wintering piping plovers occurred more frequently in accreted areas (i.e., the points and spits), which are popular spots for recreational ORV use at the Seashore (Byrne et al. 2009). The importance of protecting nonbreeding piping plovers was demonstrated in a research program by the Canadian Wildlife Service between 1998 and 2003, which primarily tracked migration patterns and survival rates of the Eastern Canada population of piping plovers. Individuals from this population were identified migrating and wintering at points along the east coast of the United States, including North Carolina (Amirault et al. 2006). The analysis of this research identified adult survival as the single most important factor influencing the population trends of this piping plover population and showed that expanding protection of nonbreeding habitat was an important factor in the recovery of the species (Amirault et al. 2006). Seashore staff will continue to monitor the abundance of nonbreeding piping plovers at the Seashore and use the data to make management decisions as to where the winter closures need to be placed.

### Risk Factors

Small populations such as the Atlantic Coast piping plover populations face a heightened risk of extinction compared to large populations because they are more vulnerable to the following: (1) random

environmental variations, such as storms; (2) reduction in genetic variations that limit a species' ability to adapt to local conditions; (3) sudden, random drops in birth and death rates; and (4) an impaired ability to find suitable mates (Lande 1988).

Given the vulnerability of the small piping plover populations in North America to random events, the persistence of the populations will depend increasingly on controlling sources of mortality to adults, eggs, and chicks throughout their range. Predators, human disturbance, and limited or blocked access to foraging habitat have been identified in past research as contributing to impaired reproductive success for plovers using the Seashore (Kuklinski et al. 1996). Thus, providing a disturbance-free environment early in the season may help piping plovers to establish territories and attract mates (Cohen 2005).

Rates and sources of mortality and disturbance, and the responses of piping plovers to disturbance in the nonbreeding season, have not been specifically assessed at the Seashore. However, it is known that piping plover foraging and roosting habitats at Cape Hatteras are used by pedestrians and ORVs outside of the breeding season (Cohen et al. 2010). Where such activity is allowed, studies conducted at several beaches in Massachusetts and New York have shown that there is the potential for piping plovers to be killed by being run over by ORVs (Melvin et al. 1994) or taken by domestic pets. Studies along the Atlantic coast (including one at the Seashore) and gulf coast have shown that the density of wintering plovers is higher in areas with limited human presence or disturbance (Cohen et al. 2008; Nicholls and Baldassarre 1990). Furthermore, disturbance to roosting and foraging birds by ORVs, unleashed pets, and pedestrians may reduce foraging efficiency or alter habitat use, thereby increasing the risk of nutritional or thermal stress (Zonick 2000; Burger et al. 2004). This type of disturbance also affects the energetic of migrating shorebirds, including piping plover and other migrating shorebirds at the Seashore. Shorebirds are some of the longest distance migratory birds and as such the energy demands of migration are extreme (Goss-Custard 1984; Harrington et al. 1991). During migration shorebirds use a variety of habitats to find food, to rest, and to avoid predators, and their survival is in part a function of the calories that individual shorebirds add by way of efficient foraging and the calories that shorebirds preserve during resting (Kersten and Piersma 1987). High quality shorebird "stop-over" habitats are those in which individual shorebirds are free to find high-quality food quickly as well as those where shorebirds can effectively rest and avoid predators between foraging bouts. Low quality habitats are those where prey items are low in density and/or where human or natural disturbance keeps birds from feeding and resting and especially where these key activities are replaced by energy-demanding avoidance behaviors such as flying and running. Disturbance to migrating shorebirds that results in the interruption of feeding and resting, combined with the energetically high-cost short flight fleeing behaviors, may impede shorebirds' ability to develop the necessary physiological condition to survive long migratory flights. Supporting this finding, comparing two beach plots open and closed to human traffic along North Carolina's Outer Banks, Collazo and others (1995) found that resting time of shorebirds was reduced by nearly 50 % in areas open to human activity.

**Weather and Tides.** Nine named hurricanes affected the Outer Banks between 1993 and 2009 (NOAA 2009). Hurricane Isabel, which hit the coast in September 2003, renewed piping plover habitat on portions of the Seashore and may have resulted in a reduction in predator populations (NCWRC 2008a). In the years immediately following the storm, piping plover numbers and productivity increased. However, there have been no significant storms since that time, and much of the created habitat is now deteriorating due to revegetation (NCWRC 2008a). No significant weather events, such as hurricanes or tropical storms, occurred during the 2006 breeding season. However, smaller, localized events may have affected nesting. Nest 4 on South Point was partially buried by high wind and blowing sand. One egg was buried by sand, and the nest was a deep cup rather than a scrape (June 29). One adult remained hunkered down on the nest during the strong winds, and the buried egg was visible again during the nest check. A strong thunderstorm was noted on the night before Nest 2 on South Beach was discovered lost; however, the loss is characterized as "unknown" because it cannot be shown conclusively that weather was the cause. Five

nests were lost to weather, predation, or abandonment during the 2007 breeding season. Nest 1, a two-egg nest on Cape Point, was lost during a Nor'easter storm. It is unknown if the eggs were blown out of the nest scrape in the 50- to 60-mile-per-hour winds, buried under the sand, or taken by a predator. In 2008, a series of sandstorms with wind gusts over 35 mph may have caused the pair from Nest 1 (Cape Point) to abandon the nest. A nest on Ocracoke was buried during a Nor'easter prior to the nest being located by resource management staff. One egg was found when compacted sand was removed from a scrape that had been maintained prior to the arrival of the storm (NPS 2009b). In 2009 there were high winds and rain prior to a single egg (first egg of a clutch) disappearing at Cape Point (NPS 2010d).

Hurricanes and other ocean storms can lead to unusually high tides, and subsequent flooding can overwash piping plover nests (Cohen et al. 2010). In May 2000, a 3-day storm produced high winds, heavy rain, and ocean overwash. One clutch at Cape Point was buried under windblown sand and abandoned, while a second was lost to flooding at Hatteras Inlet Spit (NPS 2001b). Wave action and erosion caused the abandonment of a nest in 2002 when waves undermined a protective dune, resulting in the nest being flooded by ocean overwash. The eggs were scattered from the nest and the adults did not return to them (NPS 2003d). In 2009 a four-egg nest discovered on June 8 on South Point, Ocracoke, was overwashed by spring tides on June 23 (NPS 2010d). In 2010 there was an offshore weather event that flooded South Point resulting in the loss of a three egg nest on May 26 (Muiznieks pers. comm. 2010e).

Indeed, some piping plovers that nest too close to mean high tide may lose their nests on normal high tides (Cohen et al. 2010). Storms can also result in widespread mortality of chicks (Houghton 2005). Besides these direct effects of storms on piping plover nests, flooding from extreme high tides or storm surges may alter habitat enough to render it unsuitable for nesting. This may lead to the abandonment of habitat within or between breeding seasons (Haig and Oring 1988).

**Predation.** Predation, especially by mammalian predators, continues to be a major factor affecting the reproductive success of the piping plover (Elliot-Smith and Haig 2004). Predators of eggs, chicks, and/or adults include mink (*Mustela vison*), gray fox (*Urocyon cinereoargenteus*), red fox (*Vulpes vulpes*), opossum (*Didelphis virginiana*), raccoon (*Procyon lotor*), domestic dogs (*Canis lupus familiaris*), feral and domestic cats (*Felis catus*), crows (*Corvus brachyrhynchos*), gulls (*Larus* spp.) (NPS 2008c), and birds of prey (Murphy et al. 2003). The impact of predation has been postulated to be greater on beaches with high human use because the presence of pets and trash (which may attract wild predators) is correlated with the presence of humans (USFWS 1996a, 2009a).

**Foxes outside a Piping Plover Nest Enclosure**

Credit: Richard Kuzminski / USFWS

Fox activity was recorded at all active plover nesting areas in 2001 and one late nest initiation and two nest abandonments were linked to this activity (NPS 2002b). No direct evidence of predation of chicks or eggs was recorded from 2001 through 2006, although the presence or tracks of crows, grackles (*Quiscalus* spp.), gulls, ghost crabs (*Ocyropsis quadrata*), opossum, mink, raccoon, red fox, gray fox, and domestic cats and dogs were documented within many plover breeding territories. A fox den was discovered within the Bodie Island Spit bird closure in June 2006 (NPS 2007c). During the 2007 season, eggs were missing from a plover nest at Cape Point. Staff observed both raccoon and opossum tracks in the area of the nest scrape (NPS 2008c). Predators or high winds generated by a Nor'easter storm are thought to be responsible for missing eggs and eggs observed eight feet from scrapes (NPS 2008c). In 2008, Seashore staff documented the loss of two plover chicks at Cape Point due to avian predation. One chick was taken by a gull and another by a crow. Staff also documented the presence or tracks of crows, ghost crabs, grackles, gulls, opossum, mink, raccoon, red fox, gray fox, and feral cats

within many of the piping plover breeding territories (NPS 2009b). In 2009, two chicks at Cape Point were lost to suspected opossum predation on day three (Muiznieks pers. comm. 2009). In addition to causing direct mortality, predators in piping plover habitat can also lead to piping plovers' abandoning territories within and between breeding seasons (Cohen 2005).

Ghost crabs have occasionally been implicated in the loss of nests (Watts and Bradshaw 1995) and chicks (Loefering et al. 1995). Research on ghost crabs conducted in the lab and at a breeding site at Assateague Island in Virginia suggests that crab predation is generally uncommon. However, this study indicated that the presence of ghost crabs could have a more indirect effect on plover survival. For example, adult plovers may shepherd their broods away from the foreshore, where the best forage normally exists, due to the abundance of ghost crabs at that location (Wolcott and Wolcott 1999). Poor forage was found to be a more likely contributor to chick mortality than predation by ghost crabs (Wolcott and Wolcott 1999). However, anecdotal records indicate that ghost crabs may be more of a problem in North Carolina than at sites farther north (Cohen et al. 2010). In 2007, one egg in an enclosed nest was lost to a ghost crab (NPS 2008c) and in 2008, ghost crab predation was suspected in the loss of three piping plover nests because ghost crab holes were found inside and around the nests and predator exclosures (NPS 2009b). In 2009, a two-egg nest discovered on May 22 on South Point, Ocracoke, was incubated well past its expected hatch date and was eventually predated by ghost crabs (NPS 2010d). In 2010 the loss of three nests and one chick on South Point, Ocracoke, was attributed to ghost crabs (Muiznieks pers. comm. 2010e).

**Human Activity.** Human disturbance, both direct and indirect, can adversely affect piping plovers at the Seashore. Studies on piping plovers have demonstrated that reproductive success is lower in areas with high human disturbance (Burger 1991, 1994). Research has shown that piping plover and snowy plover (*Charadrius alexandrinus*) behavior is altered by the presence of humans, which ultimately results in chicks exhibiting less time feeding, brooding, and conserving energy (Lafferty 2001a, 2001b; Page et al. 2009). Piping plovers that are subject to human disturbance spend less than 50% of their foraging time searching for prey and feeding, where undisturbed plovers can spend up to 90% of that time feeding (Burger 1994). These human-caused behavioral changes result in depleted energy reserves (Nudds and Bryant 2000), which could leave chicks more susceptible to predation or other stresses (Flemming et al. 1988; Loefering and Fraser 1995; Lafferty 2001a, 2001b; Page et al. 2009; Thomas et al. 2002). At other sites, it was documented that fledging success did not differ between areas with and without recreational ORV use (Patterson et al. 1991), although pedestrians caused a decrease in brood-foraging behavior in New Jersey (Burger 1994).

Pedestrian and nonmotorized recreational activities can be a source of both direct mortality and harassment of piping plovers. Potential pedestrians on the beach include those individuals driving and subsequently parking on the beach, those originating from off-beach parking areas (hotels, motels, commercial facilities, beachside parks, etc.), and those from beachfront and nearby residences. Vehicle impacts can extend to remote stretches of beach where human disturbance would be very slight if access were limited to pedestrians only (USFWS 1996a, 2009a).

Even with resource closures in place, protected species are still at risk. Approximately 50 to 60 occurrences of ORVs entering protected areas at the Seashore were recorded each year from 2000 to 2002. In 2003, 13 bird closure posts/signs were driven over by an ORV, and several instances of ORVs within the protected area were observed (NPS 2003d, 2004e, 2005a). A total of 105 occurrences of ORVs entering posted bird closures were recorded in 2003. This number represents a substantial increase as compared to 52 recorded in 2001 and 63 in 2002 (NPS 2004e). In 2004, 227 pedestrians and 65 vehicle tracks were reported within posted bird resource closures, including those for piping plovers. However, no plover nests were known to be disturbed, and no plover chicks were known to be lost, although four other bird

that an area has  
been closed to  
protect resources.*

---

species were killed by ORVs in 2004 (NPS 2005a). In 2005, 135 pedestrian, 57 ORV, and 13 illegal dog entries into posted bird closures were recorded (NPS 2006d). In 2006 resource staff recorded 255 pedestrian, 47 ORV, 22 dog, and 5 horse violations of bird closures (NPS 2007c). In 2007, resource staff recorded 249 pedestrian, 25 ORV, 17 dog, and 1 horse violation of bird closures (NPS 2008c). During the 2008 breeding season, resource staff recorded 80 pedestrian, 11 ORV, 5 dog, and 1 boat violation of nesting plover closures (NPS 2009b). During the 2009 breeding season, resource staff documented 192 pedestrian, 8 ORV, 19 dog, 3 horse and 3 boat violations in the prenesting closures (NPS 2010d). Most illegal entries were not witnessed but documented based on vehicle, pedestrian, or dog tracks left behind.

Disturbance from vehicles, pedestrians, and pets can cause incubating shorebirds to be flushed from their nests and in some cases pets elicited a stronger response than people (Lafferty 2001a, 2001b; Thomas 2002; Peters and Otis 2006). Flushing can affect plover behavior and viability in a number of ways (Hoopes 1993; Peters and Otis 2006). Flushing of incubating plovers from nests can expose eggs to avian predators or excessive temperatures (Elliot-Smith and Haig 2004). Repeated exposure of eggs to direct sunlight on hot days can cause overheating, which can kill avian embryos (Bergstrom 1989). In Texas, piping plovers avoided foraging on sand flats close to areas of high human use (Drake et al. 2001). Zonick (2000) found that the number of piping plovers was lower on disturbed bayside flats than on undisturbed flats, and piping plovers experienced lower foraging efficiency when disturbed. Burger (1994) and Hoopes (1993) documented a relationship between human recreation and piping plover foraging and chick survival. Other published (Smith 2007; Lott et al. 2009) and unpublished data (Houghton 2005) support the assertion that nonbreeding habitat selection is negatively correlated with human activities and development. In New York, the response of incubating adults to the presence of humans near the nest was found to be highly variable, and average nest success was unrelated to the number of disturbance sources observed within 100 meters (328 feet) of nests (Houghton 2005). Other studies on the effect of human disturbance on incubating piping plovers documented highly variable flushing distances ranging anywhere between 20 and 200 meters (66 to 656 feet) (USFWS 1996a). However, piping plovers may be more sensitive to disturbance in the Atlantic Coast southern recovery unit, as evidenced by longer flush distances in response to disturbance sources at Assateague Island National Seashore (Loegering 1992). The study on Assateague Island found that on average, incubating plovers flushed from their nests at a distance of 78 meters (256 feet), although some birds flushed when researchers were as far as 174 meters (571 feet) away, indicating a much larger flushing distance than was documented by other studies.

---

<p><i>Canid—The biological family of carnivorous and omnivorous mammals that includes the wolves, foxes, jackals, coyotes, and the domestic dog.</i></p>	<p>Unleashed pets have the potential to flush piping plovers, and these flushing events may be more prolonged than those associated with pedestrians or pedestrians with dogs on leash. For example, a study conducted on Cape Cod, Massachusetts, found that the average distance at which piping plovers were disturbed by pets was 46 meters (151 feet), compared with 23 meters (75 feet) for pedestrians. Birds flushed by pets moved farther (an average of 57 meters [187 feet]) than plovers reacting to pedestrians (an average of 25 meters [82 feet]). Duration of observed disturbance behaviors stimulated by pets was significantly greater than that caused by pedestrians (USFWS 1996a, 2009a; Hoopes 1993). In 2002, there was evidence that a dog may have been responsible for the loss of a piping plover chick at Bodie Island. When a plover brood could not be found, large canid tracks were documented in the area where the brood was often seen foraging and resting. A professional trapper with the U.S. Department of Agriculture examined the prints and verified them as domestic dog tracks. The tracks were found running in a sharp turning pattern, seeming to indicate that the dog had been engaged in a chase. Scrape marks where the dog had clawed in the sand were also evident. The chick was not observed at the site thereafter (NPS 2004e).</p>

Vehicles have been documented running over nests (Patterson et al. 1991) and birds on Assateague Island in Maryland and Virginia. In Massachusetts and New York, biologists found that 18 chicks and 2 adults were killed by vehicles between 1989 and 1993, even on beaches with only five to ten vehicles passes per day (Melvin et al. 1994). Piping plover chicks often move from the foredune area to forage along the wrack line and intertidal zone, which places them in the paths of vehicles. Chicks can end up in or near tire ruts, and sometimes have difficulty crossing or climbing out of them. The normal response of plover chicks to disturbance could increase their vulnerability to vehicles. Chicks sometimes stand motionless or crouch as vehicles approach, and their lack of rapid movement could lead to mortality (USFWS 1996a).

ORV use may also affect the beach through sand displacement and compaction (Anders and Leatherman 1987), which may lead to steeper dune profiles. This, in turn, may prove less suitable for piping plover nesting. Degradation of the wrack line is possible from as little as one vehicle pass (Leatherman and Godfrey 1979), and may negatively impact reproductive success due to the loss of important habitat used by foraging plovers (Burger 1994; Hoopes 1993). Also, the wrack line provides habitat for many beach invertebrates, which are a staple of the plover diet.

Beach and dune renourishment projects can alter the profile of beaches, causing increased erosion and habitat loss (Leatherman 1985). Important dune-creation projects have been carried out along most of the Seashore, beginning in the 1930s. These may be affecting the ability of the Seashore to support piping plovers (Harrison and Trick pers. comm. 2005). A recent study theorized that beach nourishment projects may negatively impact plover habitat because the resulting dredge spoil is often fine-grained, reducing the availability of pebbles and cobbles, which are a preferred substrate for nesting plovers (Cohen, Wunker, and Fraser 2008). Furthermore, beach stabilization prevents normal storm processes, such as overwash fan formation, thereby leading to long-term loss of moist substrate habitat and to accelerated vegetative succession in potential nesting habitat (Dolan et al. 1973). Construction of artificial structures on beaches eliminates breeding territories and may result in an increased level of predation on and human disturbance of remaining pairs (Houghton 2005).

Research, surveying, and even protective management activities can sometimes expose piping plovers to a risk of disturbance at breeding sites. For example, adult birds may be more vulnerable to predation within exclosures (Murphy et al. 2003), depending on the local predator pool and the type of exclosure used. Adults may also abandon exclosed nests more frequently (Elliot-Smith and Haig 2004).

## **SEA TURTLES**

Sea turtles are large marine reptiles found in subtropical, tropical, and temperate oceans, as well as subarctic areas. They spend the majority of their time in ocean waters, with females coming ashore only to nest on sandy beaches. Five of the seven sea turtle species existing in the world today occur in the coastal waters of North Carolina and the Seashore, and all are listed as either federally threatened or endangered. These five species are the loggerhead sea turtle, the green sea turtle, the Kemp's ridley sea turtle, the leatherback sea turtle, and the hawksbill sea turtle. Of the five species, only three are known to nest at the Seashore: the loggerhead, green, and leatherback sea turtles. The other two species, Kemp's ridley and hawksbill, are known to occur on the beaches of the Seashore only through occasional stranding, usually either due to death or incapacitation due to hypothermia, and are therefore not discussed further.

In 1978, the loggerhead turtle was federally listed as threatened (NMFS and USFWS 2008). The NMFS and the USFWS are currently considering petitions to reclassify the loggerheads in the Northwest Atlantic as endangered. Also in 1978, the green turtle was federally listed as threatened, except for the breeding populations in Florida and on the Pacific Coast of Mexico, which were listed as endangered (NMFS and

USFWS 1991). The leatherback turtle was listed as federally endangered in 1970 (NMFS and USFWS 1992a). All three species carry the same state listings as their federal listings (NCWRC 2008b).

The Seashore staff has been consistently monitoring for sea turtle nests since 1987. However, over the years both monitoring and managing techniques have changed, making data comparison difficult; therefore, only nesting data from 2000 to 2010 are presented, for these data are known to be accurate. The number of nests recorded at the Seashore from 2000 to 2010 has fluctuated greatly, with only 43 nests recorded in 2004 and 153<sup>6</sup> nests recorded in 2010, which was the highest number on record (NPS 2010a; Muiznieks pers. comm. 2010b). Of the three species that nest at the Seashore, the loggerhead turtle is by far the most numerous, comprising approximately 95% of the known nests between 2000 and 2010 (NPS 2005c, 2007e, 2008a; 2009c; 2010a; Baker pers. comm. 2009a; Muiznieks pers. comm. 2010c). Green turtles and leatherbacks breed primarily in the tropics, with only small numbers nesting at higher latitudes. Green turtles have nested regularly at Cape Hatteras, but in fewer numbers, comprising only about 5% of the nests between 2000 and 2010, while leatherback turtles have nested infrequently at the Seashore, comprising only about 1% of the nests (NPS 2005c, 2007e, 2008a; 2009c; 2010a; Baker pers. comm. 2009a; Muiznieks pers. comm. 2010b). The vast majority of sea turtle nests occur on Hatteras and Ocracoke islands, with turtles occasionally nesting on Bodie Island (NPS 2000b, 2001c, 2002c, 2003e, 2005c, 2006e, 2007e, 2008a, 2009c, 2010a).

### Loggerhead Turtle

The loggerhead sea turtle occurs throughout the temperate and tropical regions of the Atlantic, Pacific, and Indian oceans. However, the two largest nesting rookeries occur along the western rims of the Atlantic and Indian oceans. Within the United States, the loggerhead turtle nests from Texas to Virginia, with the primary nesting concentrations found on the coastal islands of North Carolina, South Carolina, and Georgia, and on the Atlantic and Gulf coasts of Florida (NMFS and USFWS 2008). Over the last decade, the total estimated nesting in the United States has fluctuated between 47,000 and 90,000 nests per year, with about 80% of the loggerhead nesting activity occurring in six counties in the state of Florida (NMFS and USFWS

**Loggerhead Turtle**

Credit: NPS

2008). Within the northern recovery unit as defined in the Loggerhead Recovery Plan (Florida/Georgia border to southern Virginia), studies of annual nest totals in South Carolina and Georgia have documented a decline in the number of nests (Ehrhart et al. 2003). However, since standardized surveying began in North Carolina in the mid-1990s, the number of loggerhead nests per season has remained fairly stable, averaging 729 nests from 1995 through 2009 (figure 12) (Godfrey pers. comm. 2005b, 2008, 2010a, 2010b).

---

<sup>6</sup> Turtle numbers for 2010 are current through October 5, 2010, with no additional nesting expected.

Source: Godfrey pers. comm. 2005b, 2008, 2010a, 2010b; seaturtle.org

**FIGURE 12. NUMBERS OF LOGGERHEAD TURTLE NESTS IN NORTH CAROLINA, 1995–2009<sup>7</sup>**

Between 2000 and 2009 the average number of loggerhead nests at the Seashore was 79, with the lowest number of nests occurring in 2004 and the highest number of nests occurring in 2008 (figure 13) (NPS 2007e, 2008a, 2009c, 2010a; Baker pers. comm. 2009a). However, in 2010 a record-breaking 146 loggerhead nests were laid at the Seashore (Muiznieks pers. comm. 2010b). While only 40 loggerhead nests were laid at Cape Hatteras in 2004, it was a poor nesting year for the entire southeast Atlantic Coast (NPS 2005c).

Loggerhead turtles spend the majority of their life at sea, with only mature females coming ashore to nest every two to three years, on average (Schroeder et al. 2003). The first turtle nests (all turtle species included) typically begin to appear at Cape Hatteras in mid-May, and the last nests are usually deposited in late August (NPS 2000b, 2001c, 2002c, 2003e, 2005c, 2006e, 2007e, 2008a, 2009c, 2010a). Although three nests were found prior to May 15 (two of which were leatherback nests), and five nests have been found after September 1, it is important to note that prior to 2008, nest patrols were conducted only from June 1 through August 31 (2001–2005), or May 15 through September 15 (2006 and 2007). Any nests laid outside of that timeframe had a greater likelihood of not being found and protected by resource management staff.

Typical nesting areas for loggerheads tend to be sandy, wide, open beaches, backed by low dunes (Miller et al. 2003). Some factors that have been found to determine nest selection include beach slope, temperature, distance to the ocean, sand type, and moisture, though results were occasionally contradictory (Miller et al. 2003).

<sup>7</sup> The NCRWC is reviewing their sea turtle database and updating the numbers with the coordinators for all North Carolina nest site locations. Many, but not all, site reviews have been completed and the numbers in this table and in the final EIS text have been updated consistent with the database revisions received from the NC Sea Turtle Coordinator at the time this final EIS was finalized. These totals reflect the best available data as of September 23, 2010. However, the North Carolina database may change slightly when the reviews of the remainder of the site locations are completed.

**FIGURE 13. NUMBERS OF LOGGERHEAD TURTLE NESTS AT CAPE HATTERAS NATIONAL SEASHORE, 2000–2010**

Although the process of nest site selection is not well understood, a successful nest must be laid in a low salinity, high humidity, well-ventilated substrate that is not prone to flooding or burying because of tides and storms and where temperatures are optimal for development (Miller et al. 2003).

At the Seashore, between 2000 and 2009 (excluding 2005 relocation data that cannot be verified), on average, 25% of the nests found (all turtle species included) were relocated from their original location by Seashore staff. Of those nests, 81% were relocated for natural causes (e.g., in areas prone to flooding [below the high tide line], in an area prone to erosion, etc.), 13% were relocated because of potential human disturbance, primarily because they were within one mile of a lighted fishing pier, 3% were relocated due to both environment and human disturbance issues, and 3% were moved during storm events later into incubation (Muiznieks pers. comm. 2010c).

The practice of relocating nests for recreation or lighting issues is not encouraged by the USFWS; therefore, beginning in 2006 nests were no longer relocated for recreational access issues and starting in 2007 nests were no longer relocated based on distance to a lighted fishing pier. As a result, the average number of nests relocated each year from 2006 to 2009 decreased to 21% of the nests found (NPS 2007e, 2008a, 2009c, 2010a).

Loggerheads are nocturnal nesters. Females emerge from the ocean and crawl toward the dune line until they encounter a suitable nest site. The female clears away surface debris with her front flippers, creating a “body pit,” and then excavates a flask-shaped nest cavity with her hind flippers. Loggerheads throughout the southeastern United States lay an average of 100 to 126 eggs per nest (NMFS and USFWS 2008). After laying her eggs, the female covers the nest with sand, and she crawls back to the sea.

Individual females may nest one to six times per nesting season, at an average interval of 12 to 15 days (NMFS and USFWS 2008). Loggerheads do not produce clutches in successive years very often with nesting years typically separated by two to three years of foraging in between (NMFS and USFWS 2008). The nest incubation period (from laying to hatching) depends on temperature and ranges from 49 to 68 days in North Carolina with an average of about 55 days (USFWS n.d.). The sex ratio of hatchlings also

depends on temperature during incubation. Below 84.6°F, more males are produced than females, and above that temperature, more females are produced (Mrosovsky 1988). For this reason, the northern part of the U.S. Atlantic population, which includes North Carolina, apparently provides a disproportionate number of males to the larger population, which is important for the stability of the population as a whole (Mrosovsky et al. 1984; Hanson et al. 1998).

Hatchling emergence occurs almost exclusively at night (Mrosovsky 1968; Witherington et al. 1990) and may occur over several nights. Upon emerging from the nest, hatchlings primarily use light cues to find and move toward the sea (Witherington and Martin 1996). Once in the water, they swim incessantly out to sea to offshore habitats where they will spend the next phase of their life history.

### Green Turtle

The green turtle is a circumglobal species in tropical and subtropical waters. The major green turtle nesting colonies in the Atlantic Ocean occur on Ascension Island, Aves Island, Costa Rica, and Surinam (NMFS and USFWS 1991). Nesting in the United States occurs in small numbers in the U.S. Virgin Islands and on Puerto Rico and in larger numbers along the east coast of Florida, particularly in Brevard, Indian River, St. Lucie, Martin, Palm Beach, and Broward counties. North Carolina is near the northern limits of its nesting area.

**Green Turtle**

Credit: Michael Lusk / USFWS

Nesting habits for the green turtle are very similar to those of the loggerhead turtle, with only slight differences.

Average clutch sizes range from 110 to 115 eggs, although this varies by population, and females produce clutches in successive years only occasionally. Usually two to four years or more occur between breeding seasons (NMFS and USFWS 1991).

From 2000 to 2010, there was an annual average of 4.3 green turtle nests at the Seashore, with a peak of nine nests in 2005 (Baker pers. comm. 2009a). In 2010, seven green turtle nests were laid at the Seashore (Muiznieks pers. comm. 2010b).

### Leatherback Turtle

Leatherback nesting grounds are distributed circumglobally, with the largest known nesting area occurring on the Pacific Coast of southern Mexico. Nesting in the United States occurs primarily in Puerto Rico, the U.S. Virgin Islands, and southeastern Florida (NMFS and USFWS 1992a).

Leatherback nesting at the Seashore was first documented in 1998 and has subsequently been documented in 2000, 2002, 2004, 2007, and 2009, totaling seven nests since 2000 (NPS 2008a, 2010a; Baker pers. comm. 2009a). No leatherback nests were documented on the Seashore in 2010 (Muiznieks pers. comm. 2010b). Since the species has a minimum of two years between nesting cycles, it is not known if more than one female of the species uses the Seashore as a nesting ground. Until 2009 the Seashore was the northernmost nesting location on record for this species (Rabon et al. 2003). However, in 2009 a leatherback nested in

**Leatherback Turtle**

Credit: USFWS

Kill Devil Hills, North Carolina, which currently represents the northernmost nest ever found from this species (Baker pers. comm. 2009c).

Leatherback nesting habits are very similar to those of the loggerhead turtle, although they tend to begin and end nesting earlier in the year than the loggerhead (NMFS and USFWS 1992a). Since 1999, the only two nests laid in April at the Seashore have been leatherbacks (NPS 2000b, 2008a). Leatherbacks are thought to migrate to their nesting beach about every two to three years (NMFS and USFWS 1992a; Miller 1997). Clutch size averages 116 eggs, and the incubation period averages 55 to 75 days. It is also reported that leatherback turtles nest an average of five to seven times per year, with an average interval of nine to ten days between nesting (NMFS and USFWS 1992a).

### **Potential Threats**

Threats to the loggerhead turtle on nesting grounds, as outlined in their recovery plan (NMFS and USFWS 2008), are representative of those also faced by green and leatherback turtles. The following discussion of threats to sea turtles is taken from the 2008 revised Loggerhead Sea Turtle Recovery Plan, which has been updated with more recent research on potential threats to these species that, in some cases, was not available at the time of the 1991 recovery plan.

**Human Presence.** The greatest threat posed by humans on the beach at night is disturbance of female turtles before they have finished nesting. From the time a female exits the surf until she has begun covering her nest, she is highly vulnerable to disturbance, especially prior to and during the early stages of egg laying. Females that abort a nesting attempt may attempt to nest again at or near the same location or select a new site later that night or the following night. However, repeated interruption of nesting attempts may cause a turtle to construct her nest in a sub-optimum incubation environment, postpone nesting for several days, prompt movement many kilometers from the originally chosen nesting site, or result in the shedding of eggs at sea. Direct harassment may also cause adult turtles to reduce the time spent covering the nest. Visitors using flashlights or lanterns or lighting campfires on the beach at night during the nesting season may deter nesting females from coming ashore and may disorient hatchlings. In addition, heavy pedestrian traffic may compact sand over unmarked nests, although the effect of this compaction has not been determined and may be negligible. Depending on the nesting substrate, pedestrian traffic over nests near the time of emergence can cause nests to collapse and result in hatchling mortality. A study in Japan found loggerhead nests laid in beach areas with pedestrian access had higher rates of dead pipped hatchlings than nests laid in restricted beach zones (USFWS and NMFS 2008).

**Recreational Beach Equipment.** The use and storage of lounge chairs, cabanas, umbrellas, catamarans, and other types of recreational equipment on the beach can hamper or deter nesting by adult females and trap or impede hatchlings during their nest-to-sea migration. The documentation of non-nesting emergences (also referred to as false crawls) at these obstacles is becoming increasingly common as more recreational beach equipment is left on the beach at night. Nesting turtles have been documented being deterred by wooden lounge chairs that prevented access to the upper beach. Additionally, there are documented reports of nesting females being trapped under heavy wooden lounge chairs and cabanas, eggs being destroyed by equipment (e.g., beach umbrellas penetrating the egg chamber), and hatchlings being hampered during emergence by equipment inadvertently placed on top of the nest (USFWS and NMFS 2008).

**Beach Vehicular Driving.** Operating privately owned vehicles on nesting beaches for recreational purposes or beach access is allowed on certain beaches in northeast Florida (Nassau, Duval, St. Johns, and Volusia counties), northwest Florida (Walton and Gulf counties), Georgia (Cumberland, Little Cumberland, and Sapelo islands), North Carolina (Fort Fisher State Recreation Area, Carolina Beach, Freeman Park, Onslow Beach, Emerald Isle, Indian Beach / Salter Path, Pine Knoll Shores, Atlantic

Beach, Cape Lookout National Seashore, Cape Hatteras National Seashore, Nags Head, Kill Devil Hills, town of Duck, and Currituck Banks), Virginia (Chincoteague NWR and Wallops Island), and Texas (the majority of beaches except for a highly developed section of South Padre Island and Padre Island National Seashore, San Jose Island, Matagorda Island, and Matagorda Peninsula where driving is not allowed or is limited to agency personnel, land owners, and/or researchers). Operating vehicles to conduct scientific research and management is generally allowed throughout the loggerhead's nesting range. The presence of vehicles on the beach has the potential to negatively impact sea turtles by running over nesting females, hatchlings, stranded turtles that have washed ashore, and nests. In addition, the ruts left by vehicles in the sand may prevent or impede hatchlings from reaching the ocean following emergence from the nest. Hatchlings impeded by vehicle ruts are at greater risk of death from predation, fatigue, desiccation, and being crushed by additional vehicle traffic. Vehicle lights and vehicle movement on the beach after dark can deter females from nesting and disorient hatchlings. Sand compaction due to vehicles on the beach may hinder nest construction and hatchling emergence from nests. Driving directly above incubating egg clutches can cause sand compaction, which may decrease hatching success and directly kill pre-emergent hatchlings. Additionally, vehicle traffic on nesting beaches may contribute to erosion, especially during high tides or on narrow beaches where driving is concentrated on the high beach and foredune (USFWS and NMFS 2008).

**Research and Conservation Management Activities.** Research and conservation management activities (e.g., nesting surveys, tagging of nesting females, nest manipulation) are tools to advance the recovery of the loggerhead; however, they have the potential to adversely affect nesting females, hatchlings, and developing embryos if not properly conducted. Research and conservation management activities should be carefully evaluated to determine their potential risks and conservation benefits. The States, in cooperation with the USFWS, have established permitting programs to ensure that proposed research and conservation activities are necessary for recovery, carried out by appropriately trained persons, non-duplicative, the least manipulative possible, and carried out in such a way to minimize chances of mortality. A low level of lethal take is authorized annually for research and conservation purposes. Under conditions where the conservation benefits (e.g., embryo survivorship, hatchling survivorship, conservation knowledge gained) are forecast to substantially outweigh the potential conservation risks, certain activities can be considered beneficial to loggerhead recovery. Most research and conservation management activities are likely to have minimal effects on nesting turtles, hatchlings, and developing embryos when conducted in accordance with established protocols designed to minimize disturbance and risk. On many beaches, surveyors use small 4-wheeled ATVs with low-pressure (<5 psi) tires that minimally impact nesting habitat. In addition, almost all surveys to count nests are conducted after sunrise when encounters with nesting turtles and emergent hatchlings are unlikely. Research activities, such as flipper and pit tagging, blood sampling, skin sampling, satellite and radio transmitter attachment, and hatchling orientation surveys, have a minimal effect on individual turtles when conducted according to established guidelines (e.g., Florida Fish and Wildlife Conservation Commission Marine Turtle Conservation Guidelines). Potential benefits from this research include important insight into population structure, species health, habitat use, and other important aspects of loggerhead biology and ecology. Nest relocation is a management technique for protecting nests that are predicted to be destroyed by environmental factors, such as erosion or repeated tidal inundation, or permitted human activities, such as beach nourishment during the nesting season. However, the unnecessary relocation of nests may result in negative impacts to eggs and hatchlings. Historically, the relocation of sea turtle nests to higher beach elevations or into hatcheries was a regularly recommended conservation management activity throughout the southeast United States. However, advances in our knowledge of the incubation environment have provided important information to guide nest management practices. Nests located where there are threats from beachfront lighting, foot traffic, and mammalian predators can be effectively managed by addressing the threat directly or by protecting the nest in situ rather than by moving the nest. In situ protection, which addresses the root causes of egg and hatchling mortality, is in keeping with Frazer's (1992) call to move away from "halfway technology." Increased understanding of the potential adverse effects associated with

nest relocation, restraint of hatchlings, and concentrated hatchling releases has resulted in less manipulative management strategies to protect nests and hatchlings. The Florida Fish and Wildlife Conservation Commission's sea turtle conservation guidelines consider nest relocation to be a management technique of last resort. At training workshops, nest monitors are advised to relocate nests only if they are certain that the nest will otherwise be lost, and if this certainty is based on extensive experience at the specific beach. Recovery Action 6111 describes development of protocols by which managers could identify threatened nests with greater precision, thereby minimizing the number of nests that are relocated (USFWS and NMFS 2008).

**Beach Erosion and Accretion.** Natural beach erosion events may influence the quality of nesting habitat. Nesting females may deposit eggs at the base of an escarpment formed during an erosion event where they are more susceptible to repeated tidal inundation. Erosion, frequent or prolonged tidal inundation, and accretion can negatively affect incubating egg clutches. Short-term erosion events (e.g., atmospheric fronts, Nor'easter storms, tropical storms, and hurricanes) are common phenomena throughout the loggerhead nesting range and may vary considerably from year to year. Sea turtles have evolved a strategy to offset these natural events by laying large numbers of eggs and by distributing their nests both spatially and temporally. Thus, the total annual hatchling production is never fully affected by storm-generated beach erosion and inundation, although local effects may be high. For example, storm-induced mortality in the Dry Tortugas Recovery Unit has been high during years of high tropical storm activity and may limit recovery. However, human activities along coastlines can accelerate erosion rates, interrupt natural shoreline migration, and reduce both the quantity and quality of available nesting habitat. During erosion events, some nests may be uncovered or completely washed away. Nests that are not washed away may suffer reduced reproductive success as the result of frequent or prolonged tidal inundation. Eggs saturated with seawater are susceptible to embryonic mortality. However, in spite of the potential for reduced hatching success, loggerhead eggs can successfully survive periodic tidal inundation. Studies have shown that although frequent or prolonged tidal inundation resulted in fewer emergent hatchlings, occasional overwash of nests appeared to have minimal effect on reproductive success. Accretion of sand above incubating nests may also result in egg and hatchling mortality (USFWS and NMFS 2008).

**Light Pollution.** Both nesting and hatchling sea turtles are adversely affected by the presence of artificial lighting on or near the beach. Experimental studies have shown that artificial lighting deters adult female turtles from emerging from the ocean to nest. A 1986 study noted that loggerheads aborted nesting attempts at a greater frequency in lighted areas. Because adult females rely on visual brightness cues to find their way back to the ocean after nesting, those turtles that nest on lighted beaches may become disoriented (unable to maintain constant directional movement) or misoriented (able to maintain constant directional movement but in the wrong direction) by artificial lighting and have difficulty finding their way back to the ocean. In some cases, misdirected nesting females have crawled onto coastal highways and have been struck and killed by vehicles. Hatchlings exhibit a robust sea-finding behavior guided by visual cues, and direct and timely migration from the nest to sea is critical to their survivorship. Although the mechanism involved in sea-finding is complex, involving cues from both brightness and shape, it is clear that strong brightness stimuli can override other competing cues. Hatchlings have a tendency to orient toward the brightest direction as integrated over a broad horizontal area. On natural undeveloped beaches, the brightest direction is commonly away from elevated shapes (e.g., dune, vegetation, etc.) and their silhouettes and toward the broad open horizon of the sea. On developed beaches, the brightest direction is often away from the ocean and toward lighted structures. Hatchlings unable to find the ocean, or delayed in reaching it, are likely to incur high mortality from dehydration, exhaustion, or predation. Hatchlings lured into lighted parking lots or toward streetlights are often crushed by passing vehicles. Uncommonly intense artificial lighting can draw hatchlings back out of the surf. Although the attributes that can make a light source harmful to sea turtles are complex, a simple rule has proven useful in identifying lights that pose potential problems for sea turtles. Researchers propose that artificial light sources are "likely to cause problems for sea turtles if light from the source can be seen by an observer

standing anywhere on the beach.” This visible light can come directly from any glowing portion of a luminaire, including the lamp, globe, or reflector, or indirectly by reflection from buildings or trees that are visible from the beach. Bright or numerous light sources, especially those directed upward, will illuminate sea mist and low clouds, creating a distinct sky glow visible from the beach. Field research suggests hatchling orientation can be disrupted by the sky glow from heavily lighted coastal areas even when no direct lighting is visible. The ephemeral nature of evidence from hatchling disorientation and mortality makes it difficult to accurately assess how many hatchlings are misdirected and killed by artificial lighting. Reports of hatchling disorientation events in Florida describe several hundred nests each year and are likely to involve tens of thousands of hatchlings. However, this number calculated from disorientation reports is likely a vast underestimate. Independent of these reports, researchers surveyed hatchling orientation at nests located at 23 representative beaches in six counties around Florida in 1993 and 1994 and found that, by county, approximately 10 to 30% of nests showed evidence of hatchlings disoriented by lighting. From this survey and from measures of hatchling production, the number of hatchlings disoriented by lighting in Florida is calculated in the range of hundreds of thousands per year (USFWS and NMFS 2008).

**Beach Debris.** Hatchlings often must navigate through a variety of obstacles before reaching the ocean. These include natural and human-made debris. Debris on the beach may interfere with a hatchling’s progress toward the ocean. Research has shown that travel times of hatchlings from the nest to the water may be extended when traversing areas of heavy foot traffic or vehicular ruts; the same is true of debris on the beach. Hatchlings may be upended and spend both time and energy in righting themselves. Some beach debris may have the potential to trap hatchlings and prevent them from successfully reaching the ocean. In addition, debris over the tops of nests may impede or prevent hatchling emergence.

**Natural Catastrophes.** Periodic, short-term, weather-related erosion events (e.g., atmospheric fronts, Nor’easter storms, tropical storms, and hurricanes) are common phenomena throughout the loggerhead nesting range and may vary considerably from year to year. It was reported that 24.5% of all loggerhead nests laid on Deerfield Beach, Florida, in 1992 were lost or destroyed by Hurricane Andrew as a result of storm surge (NMFS and USFWS 2008). Similarly, Martin (1996) reported a 22.7% loss of total loggerhead nest production on the southern portion of Hutchinson Island, Florida, during the passage of Hurricane Erin in 1995. Ehrhart and Witherington (1987) reported a 19% loss of loggerhead nests at Melbourne Beach, Florida, after a 5-day Nor’easter storm in 1985. In Georgia, 16% of loggerhead nests were lost to tropical storm systems in 2001; nest loss was particularly high on Sapelo (54%) and Little Cumberland islands (28%). On Fisher Island in Florida, it was reported that hatchling emerging success decreased significantly following Hurricane Andrew in 1992 (NMFS and USFWS 2008). They found that hatchlings were unable to emerge from nests where sand had accreted in large quantities and that these hatchlings probably died from asphyxiation or exhaustion while struggling to emerge from the nests. Sea turtles have evolved a strategy to offset these natural events by laying large numbers of eggs and by distributing their nests both spatially and temporally.

**Threat Occurrences at Cape Hatteras National Seashore.** The following data and discussions are from the Seashore’s annual sea turtle reports, 1999 to 2009, and include all turtle species (NPS 2000b, 2001c, 2002c, 2003e, 2005c, 2006e, 2007e, 2008a, 2009c, 2010a; Sayles pers. comm. 2005).

The majority of turtle nest losses at the Seashore from 1999 to 2009 were weather related, particularly due to hurricanes and other non-tropical storms. Nest losses resulted from storms washing them away, burying them under feet of sand, or drowning them in the flooding tides. During this time period, seven hurricanes made landfall and impacted nests. In 2003, 34 of 87 nests hatched before Hurricane Isabel hit. Afterward, none of the remaining 52 nests (60%) could be found, and the water and sand movement along the beaches left no evidence of their previous existence. In 2006, 30% of the nests (23 of 76 nests) were either lost to heavy seas or drowned by flooding tides. In 2007, five nests (6%) were lost; in 2008, six

nests (5%) were lost and another 16 nests experienced decreased nest success due to two tropical storms. In 2009, six nests (6%) were lost to storms and another 25 experienced a severe decrease in nest success due to individual storms. Additionally, many other nests over the years have experienced reduced hatching success due to storm overwash that could not be correlated to any one particular storm event.

Foxes were first seen at the Seashore in 1999 and on Hatteras Island in the winter of 2001–2002. Foxes disturbed or destroyed turtle nests in 5 of the 11 years between 1999 and 2009, with the number of nests disturbed or destroyed ranging from one to nine nests per year. Ghost crab predation has been reported sporadically from 1999 to 2009, with 0 to 27 nests per year recorded as having either ghost crab holes burrowed deep into the nest cavity and/or eggshell fragments found on top of the sand in association with crab tracks.

Pedestrian tracks have been recorded inside closures, with counts ranging from 8 to 92 intrusions per year. Pedestrians disturbed or destroyed two to six nests per year from 1999 to 2009 by digging at the nest site; however, no pedestrian disturbances occurred in 2003, and no data were available for 2005.

Many, but not all, ORV users respect sea turtle nest protection areas. Since 1999, recorded violations of sea turtle nest protection areas by ORVs have ranged annually from 13 to 45 sets of tracks inside closures, though a total of 130 sets of tracks were documented in 2000 and 102 sets of tracks were documented in 2001. Most, but not all, of these ORV violations occurred when ORVs drove in front of nest areas during periods of low tide. Incidents of ORVs causing property damage to signs, posts, and twine marking the sea turtle nest protection areas have also been documented. From 1999 to 2009, the number of incidents where ORVs caused property damage generally ranged from 3 to 9 incidents annually, although a total of 28 incidents were recorded in 2000 and a total of 146 incidents were recorded in 2001. ORVs drove over four to five nests per year from 2000 to 2002; however, the nests survived. Two nests in 2007 and one nest in 2008 were known to have been run over by ORVs before they were found during the morning turtle patrol and fenced off. Of these three nests, the 2008 nest and one of the 2007 nests appeared undamaged; however, four eggs were crushed in the second 2007 nest. In 2004, a total of ten hatchlings were killed by vehicles in two separate incidents.

In 2009, despite operating under the consent decree, requiring expanded buffers be implemented after acts of deliberate closure violations/vandalism, two occurrences of deliberate violations were recorded (NPS 2010a). In 2010, an ORV driving on the beach at night, in violation of the consent decree, struck and killed a nesting female loggerhead turtle during the nighttime hours between June 23 and June 24. The turtle had crawled out of the ocean and attempted to lay a nest between ramps 70 and 72 on Ocracoke Island. The turtle was hit by an ORV and dragged approximately 12 feet, causing fatal injuries to the turtle. The turtle was found dead by NPS turtle patrol at 6:10 a.m. on June 24. This particular incident is believed to be the first time documented that a nesting sea turtle has been killed by an ORV at the Seashore (NPS 2010b).

**Nesting Female Loggerhead Killed by ORV in 2010**

NPS photo of scene showing turtle carcass (between ORV tracks) and drag marks. Oval objects extending from the turtle are eggs.

Source NPS 2010b

Dogs disturbed or destroyed two nests in 2000, and 5 to 60 sets of dog tracks per year have been recorded inside closures. In 2008, cats were documented preying on emerging hatchlings at several nests, all within the villages. This was the first year in which this was documented; however, 10 to 50 sets of cat tracks per year were counted inside turtle closures from 2000 to 2002 and in 2009 cat tracks were found within at least 20 turtle closures, most commonly in the village areas.

The total number of pedestrian, vehicle, and pet violations are conservative estimates, for often the actual numbers could not be determined. Footprints and tracks are often recorded as a single violation, when an undeterminable number of tracks through an area may actually represent multiple violations. Also, tracks below the expanded nest closures are often washed out by the tide before being discovered by the turtle patrol.

Documented beach fires totaled 174 in 2000 and 773 in 2001. Such fires may misdirect adults and emergent hatchlings. In 2006, an adult turtle crawl was discovered going into the coals of a beach fire, and in 2007, a turtle approached a beach fire, which visitors quickly extinguished prior to the turtle laying her nest about 2 feet from the fire site. In 2008, several hatchlings were found entering a fire and were recovered and released. It was unknown how many died prior to the hatchlings being noticed. Hatchlings being misdirected by lights from villages and other human structures is a common occurrence at the Seashore. In 2009, the NPS documented tracks which indicated that a nesting female sea turtle crawled up to a still-warm fire pit, turned around, and went back into the water, as noted in the annual report (NPS 2010a).

There have also been documented reports in 2000, 2001, 2007, 2008, and 2009 and an unconfirmed report in 2006, of adult turtles aborting nesting attempts when visitors approached the turtles with flashlights,

vehicle lights, or flash photography. Because the beaches are not patrolled 24 hours a day, it is likely that more disturbances of this nature occur but go undocumented.

Since 2001, Seashore staff members have been tying notices to personal property found on the beach after dawn, advising owners of the threats to nesting sea turtles, and then removing the items, when possible, if they remain on the beach 24 hours after tagging (NPS 2008a).

### SEABEACH AMARANTH

Seabeach amaranth is an annual plant native to barrier-island beaches along the U.S. Atlantic Coast, including those within the Seashore. Historically, seabeach amaranth was found in nine states, from Massachusetts to South Carolina. It was federally listed as threatened by the USFWS in 1993 because of its vulnerability to human and natural impacts and the fact that it had been eliminated from two-thirds of its historic range (USFWS 1996b). Since its listing, seabeach amaranth has reappeared in several states and is currently found in New York, New Jersey, Delaware, Maryland, Virginia, North Carolina, and South Carolina. Despite its reappearance in several states, the plant remains highly vulnerable to the threats that caused its listing, and in some states, populations continue to decline (USFWS 2005b).

**Seabeach Amaranth**

Credit: Gene Nieminen / USFWS

This species is listed as threatened by the State of North Carolina (NCNHP 2006). Within North Carolina, from 2002 to 2003, the number of plants increased from 5,700 to 9,300 along 112 miles of beach (Cohen et al. 2010), only a fraction of the approximately 40,000 plants reported in the late 1980s and 1995 (Suiter pers. comm. 2005). Within the Seashore, seabeach amaranth numbers ranged from 550 to nearly 16,000 plants between 1985 and 1990 (table 25). However, in the last 10 years a maximum of only 93 plants was observed in 2002. More recently, only one plant was found in 2004 and two plants in 2005. Since 2005, no plants have been found within the Seashore.

**TABLE 25. NUMBERS OF NATURALLY OCCURRING PLANTS OF SEABEACH AMARANTH AT CAPE HATTERAS NATIONAL SEASHORE, 1985–2008**

	1985	1986	1987	1988	1990	1993	1994	1995

Source: NPS 2009e; NPS 2010e; Broili pers. comm. 2010

Seabeach amaranth is a low-growing annual, with stems that trail along the ground but do not root. The stems are reddish in color, fleshy, grow to 4 to 24 inches in length, and have round, fleshy, dark green leaves (0.4 to 0.6 inches long) clustered near the tips. Plants must recruit annually from seed banks, either in place or from other source populations dispersed by wind, water, or sediments distributed by anthropogenic (human) factors, such as beach renourishment (Jolls et al. 2004). Seeds must be scarified (the seed coat broken by nicking or abrasion) or cold stratified (chilling for weeks) before germination can occur (Cohen et al. 2010). Germination takes place from April through July; initially, a small sprig forms, which soon begins to branch into a clump. At the Seashore, seedlings are usually visibly detectable beginning in June (Lyons pers. comm. 2005). Plants are typically 10 to 12 inches in diameter, consisting of 5 to 20 branches, though occasionally a clump may get as large 3 feet or more across, with more than 100 branches (USFWS 1993; NJDEP 2005).

Flowering begins when plants are of sufficient size, often in June but more typically in July, and continues until the plants die in late fall or early winter. The species is a prolific seed producer, with seed production beginning in July or August and usually reaching a peak in September. Seed production continues until the plant dies. The seeds are relatively large (0.1 inch), believed to be viable for long periods of time (decades), and contained in indehiscent utricles (a fruit pouch that does not split open spontaneously at maturity to release its seed). Though the utricles are normally indehiscent, it is not unusual to see them splitting open, either before or after their detachment from the plant. Splitting or fragmentation of the utricle occurs under conditions of agitation (by wind), abrasion (by sand), or simple loss of integrity over time (USFWS 1996b).

Seed dispersal may occur by wind or water, and naked seeds do not disperse nearly as far from the parent plants as seeds retained in utricles. Seeds may also be dispersed by human activities, such as beach replenishment programs. Many utricles remain attached to the plant and never disperse, allowing seeds and fruit to pile up around the bases of the parent plants. This primarily occurs at the end of the growing season when the plant dies (USFWS 1996b).

Seabeach amaranth occupies a fairly narrow habitat niche. It is found on sandy ocean beaches, where its primary habitat consists of overwash flats at accreting ends of islands, and at the sparsely vegetated zone between the high-tide line and the toe of the primary dune on non-eroding beaches. It is intolerant of competition and does not occur on well-vegetated sites. It is also intolerant of even occasional flooding or overwash. Populations are occasionally found in other habitats, including back dunes, soundside beaches, blowouts in foredunes, and beach-replenishment areas, but these populations tend to be small and temporary (USFWS 1996b; NJDEP 2005). In general, in order to survive, this species needs extensive areas of barrier island beaches and inlets, functioning in a relatively natural and dynamic manner, to allow it to move around in the landscape, occupying suitable habitat as it becomes available (USFWS 1993).

Since 2000, locations where seabeach amaranth has been found within the Seashore include the upper, dry-sand flats at Cape Hatteras Point (Cape Point and South Beach), in a line of small dunes adjacent to the flats at Hatteras Inlet Spit, at Bodie Island Spit, and at the base of dunes on the beach on the northern half of Ocracoke Island. Most areas where the plants have been found were either in established bird closures or other areas closed to vehicular traffic (NPS 2001d, 2001b, 2005a). Despite continuous protection (through the establishment of summer and winter resource closures) of the area on Bodie Island Spit where the plants were found in 2004 and 2005, as well as the area on Cape Point where the plant was historically found, no plants have been found in the Seashore since 2005. Additionally, large portions of the historic range of the plant at Hatteras Inlet Spit no longer exist due to continued erosion. While it is thought that the plant may possibly be extirpated from the Seashore (NPS 2009e), it should be noted that since plants are not evident every year, but may survive in the seed bank, populations of seabeach amaranth may still be present even though plants are not visible for several years (USFWS 2007d).

The predominant threat to seabeach amaranth is the destruction or alteration of suitable habitat, primarily because of beach stabilization efforts and storm-related erosion (USFWS 1993). Other important threats to the plant include beach grooming and some forms of “soft” beach stabilization, such as sand fencing and planting of beach-grasses; vehicular traffic, which can easily break or crush the fleshy plant and bury seeds below depths from which they can germinate; and predation by webworms (caterpillars of small moths) (USFWS 1993). Webworms feed on the leaves of the plant and can defoliate the plants to the point of either killing them or at least reducing their seed production. Beach vitex (*Vitex rotundifolia*) is another threat to seabeach amaranth, as it is an aggressive, invasive, woody plant that can occupy habitat similar to seabeach amaranth and outcompete it (ISSG 2009).

## STATE-LISTED AND SPECIAL STATUS SPECIES

This section addresses the habitat, diet, reproduction, population trends, and impacts on several species of shorebirds that are listed or recognized as special status species by the State of North Carolina but are not federally listed as endangered or threatened. Most of these species breed on Cape Hatteras, as well as in other areas of North Carolina. Species described include American oystercatcher; four species of colonial waterbirds, including gull-billed terns, least terns, common terns, and black skimmers; Wilson’s plover; and red knots. The latter species breeds in the Arctic and uses the Seashore as a stopover during its annual migration.

### AMERICAN OYSTERCATCHER

The American oystercatcher is a large (16–18 inches long, 14–24 ounces) and conspicuous shorebird with long pink legs and a long, bright reddish-orange bill. The upper body is covered with black feathers that contrast with white feathers on the breast and sides. The sexes are similar in appearance, although females are slightly larger than males.

**American Oystercatcher**

Credit: Steven J. Dinsmore

Oystercatchers are restricted to the coastal zone throughout the year, where they inhabit saltmarshes and coastal islands along the southeastern United States coast (Schulte et al. 2007; Nol et al. 2000). They feed primarily on bivalves, mollusks, worms, and other marine invertebrates that inhabit intertidal areas (Nol and Humphrey 1994; Cohen et al. 2010). This specialized diet is the reason that American oystercatchers are primarily found in coastal areas that support intertidal shellfish beds (Schulte et al. 2007).

Oystercatchers form pair bonds in February and early March. Courtship takes place in saltmarshes and on dunes, beaches, dredge spoils, and oyster bars. They breed from March to August along the Atlantic Coast, from Massachusetts to Florida, in relatively high, open, sandy areas with sparse to no vegetation (Nol and Humphrey 1994; Cohen et al. 2010). They also breed along the Gulf Coast from Florida to Mexico and winter from central New Jersey south to the Gulf of Mexico (Simons and Schulte 2008).

### American Oystercatcher in North Carolina

A 2007 breeding season survey estimated North Carolina’s summer American oystercatcher population at 717 individuals, with 339 breeding pairs (Simons and Schulte 2008), and a 2005 survey estimated a winter population of oystercatchers in North Carolina at 647 birds (Brown et al. 2005). Cape Lookout and Cape Hatteras national seashores are estimated to support 90 breeding pairs (Simons and Schulte 2008), or 27% of the state’s breeding oystercatchers. Barrier islands continue to be an important habitat, and supported 43% of the oystercatchers in North Carolina in 2007. Most of the barrier island nesters were

found on undeveloped islands, although inlet spits on many developed islands continued to support nesting birds (NCWRC 2008b). Oystercatcher reproductive success in North Carolina has been extremely low, as studies conducted between 1995 and 2008 demonstrated an average of 0.31 chicks per nesting pair surviving to fledge (Simons and Schulte 2008). Other studies conducted at Cape Lookout National Seashore between 1997 and 1999 documented fledge rates ranging from as low as 0.04 to 0.15 (Davis et al. 2001). The American oystercatcher is classified as a Species of High Concern in the U.S. Shorebird Conservation Plan because of its small population (11,000 individuals), widespread habitat loss, and the threats it faces both during the breeding and nonbreeding seasons (Schulte et al. 2007). The oystercatcher was designated as a Species of Special Concern in North Carolina on May 1, 2008 (Pipkin pers. comm. 2009), and is listed on the USFWS 2008 Birds of Conservation Concern (USFWS 2008b).

### Habitat Description

In North Carolina, oystercatchers generally nest on sandy sites characterized by open substrate and little vegetation, far from the water, and slightly elevated to afford at least a 180° view (Nol and Humphrey 1994; Shields and Parnell 1990; Cohen et al. 2010). However,

**Foraging and Nesting Habitat**

Credit: NPS – Cape Hatteras National Seashore

**Sand Flats**

Credit: NPS – Cape Hatteras National Seashore

there is evidence that oystercatchers have begun to use less traditional nesting habitats such as dredge spoil islands and vegetated marshes (McGowan et al. 2005; Traut et al. 2006). A breeding season study in Virginia documented that over half of the oystercatcher breeding pairs were located on storm-deposited shell rakes (Wilke et al. 2005). Elevation of nest habitat and distance to the water are both important to nest success because nests can be destroyed by tidal flooding (Lauro and Burger 1989). Oystercatchers are more common in habitat with few predators or no terrestrial predators (e.g., feral or domestic predators) (Nol and Humphrey 1994). Oystercatcher foraging habitats include oyster and mussel bars and intertidal sand flats and mudflats. Winter and summer foraging habitats are similar (Nol and Humphrey 1994; Nol et al. 2000).

### Diet

The elongated and laterally compressed bill of the oystercatcher is especially suited to allow the bird to prey upon and open marine bivalves (class Bivalvia), including oysters (family Ostreidae), soft-shell clams (*Mya arenaria*), razor clams (*Ensis directus*), stout razor clams (*Tagelus plebeius*), and ribbed mussels (*Geukensia demissa*). Other items the oystercatcher consumes include marine worms (phylum Platyhelminthes), mole crabs (*Emerita talpoida*), sandworms (*Nereis virens*), limpets (order Patellogastropoda), jellyfish (phylum Cnidaria), sea urchins (phylum Echinoderma), and crabs (order Decapoda) (Bent 1929; Johnsgard 1981; Nol 1989; Nol and Humphrey 1994).

## Breeding Biology

The major stages of the oystercatcher nesting cycle include the following: establishment and holding of nesting territories, courtship and copulation, nest scraping and nest building, egg laying and incubation, chick rearing, and fledging. Breeding pairs of oystercatchers begin nesting in late February and early March by establishing and holding a nesting territory and then scraping multiple shallow depressions in the sand. Eventually, they choose one scrape to build a nest (Nol and Humphrey 1994; McGowan et al. 2005). Nests are 1.5–2.5 inches deep and 7.0–8.0 inches across. They may contain shell fragments, dead plants, small stones, and beach debris (Baicich and Harrison 1997). Oystercatchers are typically monogamous and may mate for life (Nol and Humphrey 1994).

Oystercatchers can nest in proximity to colonial waterbirds, including but not limited to common tern, least tern, and black skimmer.

**American Oystercatcher Chicks Near Wrack**

Credit: Ted Simons

Both sexes incubate three eggs (rarely two or four) for 24–28 days, and incubation may begin after the second egg is laid (Nol and Humphrey 1994) or after the last egg (Baicich and Harrison 1997).

Oystercatchers will re-nest if eggs or nestlings are lost early in the season. Both adults brood nestlings, which crouch motionless when alarmed, making them difficult to see. Nestlings remain in the nest for 1–2 days and then move with adults within their nesting territory or into nearby foraging areas, which can be 150 to 600 feet away, depending on the habitat. Chicks fledge in about 35 days, but fledglings rely on adults almost entirely until they are 60 days old (Nol and Humphrey 1994).

## American Oystercatcher Breeding Performance at Cape Hatteras National Seashore

At the Seashore, the oystercatcher population has experienced declines in numbers of breeding pairs since the 1990s. As seen in table 26 and figure 14, from 1999 to 2006, the number of nesting pairs declined 44% from 41 to 23 pairs on Ocracoke, Hatteras, Bodie, and Green islands (table 26).

From 1999 to 2010 on Ocracoke Island, there were a total of 94 nesting pairs, 133 nests, 60 hatched nests, 47 fledged chicks, and a fledge rate of 0.46. From 1999 to 2010 on Hatteras Island, there were a total of 207 nesting pairs, 273 nests, 120 hatched nests, 95 fledged chicks, and a fledge rate of 0.51. From 1999 through 2010 on Bodie Island, there were a total of 30 nesting pairs, 44 nests, 10 hatched nests, 6 fledged chicks, and a fledge rate of 0.20. From 2004 through 2010 on Green Island, there were a total of 15 nesting pairs, 19 nests, 11 hatched nests, 15 fledged chicks, and a fledge rate of 0.98 (Muiznieks pers. comm. 2010a; table 27).

NOTE: Data available only for years listed.

b = Average.

Of all known breeding sites at the Seashore, chicks on Green Island have the greatest chances of surviving until fledging, with an average fledge rate of 0.98, which is approximately double the fledge rate on Ocracoke or Hatteras islands and more than four times the fledge rate on Bodie Island. The percentage of nests that survived and successfully hatched has also been substantially lower on Bodie Island when compared to nest survival on the other three islands (table 27). However, since 2007, the number of nesting pairs increased from two to four on Bodie Island and 2008 marked the first time an oystercatcher chick fledged since 2002. In 2010, these numbers declined with only one nesting pair and no fledged chicks on Bodie Island (table 27).

Since 1999, the number of nesting pairs at the Seashore has generally declined but has remained stable at 23 nesting pairs for the last five years (see figure 14). The annual number of fledged chicks has ranged from a low of 5 in 1999 to a high of 30 in 2010, which represents the first time the fledge rate exceeded 1.0 at the Seashore (where the lines cross on the figure). The rapid decrease in chick survival in 2002 is thought to correspond to the arrival of the fox as a predator on Hatteras Island. The advent of predator control efforts at the Seashore in 2003 is thought to be a contributing factor to the noticeable increase in chick survival between the 2003 and 2004 seasons (Simons and Schulte 2008). However, in the absence

of hurricane events (which sometimes provide improved habitat), a recent demographic model projected a rapid decline for oystercatchers in North Carolina in the next 50 years (Simons and Schulte 2008).

### Nonbreeding Oystercatchers

American oystercatcher migration generally begins at the end of August and continues through November. American oystercatchers are short-distance, partial migrants and generally winter along the southeast coast of the United States (Schulte et al. 2007; Nol et al. 2000).

Winter and migratory habitat appear to be similar to breeding habitat, although additional research is needed to determine preferred habitat in the winter, especially for birds on migration. Limited observations indicate that winter birds roost on open ground without vegetation in areas near foraging habitat (Nol and Humphrey 1994). A study conducted during the winter of 2002–2003 found that oystercatchers commonly use shell rakes as winter roost sites (Brown et al. 2005). Other habitat types used by wintering oystercatchers include sand islands, inlet beaches, sand spits, edges and interior mudflats on marsh islands, and occasionally docks and jetties (Brown et al. 2005; Schulte et al. 2007).

The NPS SECN Winter Monitoring Program conducted a more comprehensive study on wintering shorebirds. Pilot implementation of this SECN shorebird monitoring protocol at the Seashore began in mid-July 2006. Results for the oystercatcher, which are depicted on figure 15, are discussed below.

Source: Byrne et al. 2009

**FIGURE 15. MONTHLY OBSERVATIONS OF AMERICAN OYSTERCATCHERS (AMOY) PER 30-MINUTE SAMPLING EVENT AT CAPE HATTERAS NATIONAL SEASHORE, 2006–2007**

From July 2006 through April 2007, the majority of American oystercatchers were observed in foreshore and mudflat / algal flat habitat types (figure 16). American oystercatchers appeared to use the foreshore during both tidal extremes and used the mudflat / algal flat habitat primarily during high tide. The highest numbers of birds appeared to occur in August, and the data from the first year of pilot study show that the Seashore does not appear to have a wintering population of oystercatchers, which is shown in the American oystercatcher numbers between 2008 and 2010 (Muiznieks pers. comm. 2010e).

**FIGURE 16. NUMBERS OF AMERICAN OYSTERCATCHER (AMOY) OBSERVATIONS BY HABITAT TYPE AND TIDAL STAGE AT CAPE HATTERAS NATIONAL SEASHORE, 2006–2007**

Subsequent monitoring of oystercatchers between August and April 2007–2009 by Seashore staff indicated similar results, with very few birds observed from December through February (see figure 17). Figure 17 may be misleading in that the surveys conducted by Seashore staff were only conducted at the points and spits to comply with monitoring requirements for the piping plover. Oystercatchers will forage along the entire shoreline without preference for the points or spits and are therefore probably underestimates of the numbers occurring on the Seashore during the months represented.

Source: Byrne et al. 2009

Note: Data represented in this figure were only collected at the points and spits and most likely underestimate the number of oystercatchers present at the Seashore during these months.

### Risk Factors to American Oystercatchers

In addition to direct habitat loss, the American oystercatcher faces pressure from recreational disturbance, increases in predators, potential contamination of food resources, and alteration of habitat through beach stabilization (Schulte et al. 2007). Causes of American oystercatcher nest failure on the Outer Banks from 1998 through 2008 could not be determined for 49% of nest failures. However, the causes of failure that could be determined were mammalian predation (54%), ghost crab predation (3%), avian predation (4%), direct human disturbance (4%), abandonment (6%), and overwash (29%) (Simons and Schulte 2008).

**Human Activity.** Oystercatchers need large, undisturbed beach areas for successful nesting. Research has shown that disturbance by pedestrians, kayakers, vehicles, and unleashed pets can cause the abandonment of nest habitat as well as direct loss of eggs and chicks (Cohen et al. 2010; Sabine et al. 2006, 2008; Toland 1999; Hodgson et al. 2008). Studies of the effects of humans and vehicles on American oystercatchers have indicated lower nest survival and higher chick mortality in places with higher levels of disturbance (McGowan 2004; Sabine 2005; Simons and Schulte 2008).

Studies in Europe on the European oystercatchers (*Haematopus ostralegus*), in the same genus as American oystercatcher and closely related, have shown reduced foraging efficiency and lower rates of chick feeding in disturbed versus undisturbed habitats (Verhulst et al. 2001). In the winter, disturbance caused European oystercatchers to reduce foraging, although the behavioral response of avoidance lessened as the winter progressed (Stillman and Goss-Custard 2002). A study at Cape Lookout National Seashore documented lower nesting success for oystercatchers in areas where human disturbance was higher and also noted that oystercatchers avoided nesting in areas with high levels of human activity (Davis 1999). Another study in North Carolina found evidence that oystercatcher nests that were frequently disturbed by beach vehicles suffered higher rates of nest predation (McGowan and Simons 2006).

In addition to direct impacts or mortality, reasons for lower reproductive success in areas of high disturbance may include reduced time spent foraging (Sabine et al. 2008; Verhulst et al. 2001; Stillman and Goss-Custard 2002), thermal stress to eggs caused by a lack of incubation when reacting to disturbance (Sabine 2006; Verhulst et al. 2001), and expenditure of energy reserves during flushing or defensive displays (Toland 1999; Nudds and Bryant 2000; Stillman and Goss-Custard 2002). Studies at Cumberland Island National Seashore in Georgia found that foraging behavior was lower in the presence of vehicular activity, which could alter chick provisioning and ultimately affect chick survival. Researchers recommended prohibiting beach driving in oystercatcher territories when chicks are present (Sabine 2005). Research on flush responses of oystercatchers to human disturbance indicates that protection of this species requires a buffer distance of up to 656 feet from nesting areas (Cohen et al. 2010; see table 28).

**TABLE 28. BUFFER DISTANCES RECOMMENDED FOR AMERICAN OYSTERCATCHERS**

Buffer Distance	Source	Disturbance Types	Behavior/Location	Region
450 feet (137 meters)	Sabine 2005	Pedestrians, ORVs / other vehicles, boats, pets	Nesting	Cumberland Island National Seashore, Georgia
492 feet (150 meters)	Sabine 2005	Pedestrians, ORVs / other vehicles, boats, pets	Brood rearing	Cumberland Island National Seashore, Georgia
100 feet (30 meters)	Maine Department of Environmental Protection 2009	Development, vegetation removal	Feeding Area <sup>a</sup>	Maine
250 feet (76 meters)	Maine Department of Environmental Protection 2009	Development, vegetation removal	Roosting Area <sup>b</sup>	Maine
338 feet (103 meters)	Rodgers and Schwikert 2002	Personal watercraft	Nonbreeding adult foraging and loafing	West and east coasts of Florida
656 feet (200 meters)	Cohen et al. 2010	All human disturbance	Nesting	Cape Hatteras National Seashore

<sup>a</sup> Shorebird feeding areas include the intertidal zone and a 100-foot adjacent buffer area.

<sup>b</sup> Shorebird roosting areas include the intertidal zone, the roosting area, and a 250-foot area adjacent buffer area.

The reproductive success of oystercatchers at Cape Hatteras has been impacted by vehicle and pedestrian disturbance. From 1999 to 2008, 48% of chicks in full beach closures on Cape Hatteras survived to fledging, while only 24% survived when the beach had an open lane for vehicles and pedestrians (Simons and Schulte 2008; see figure 18). Seashore staff also documented that the highest hatching rate (87%) was found at sites that did not have ORV use or concentrated pedestrian use (NPS 2005e).

Source: Simons and Schulte 2008

**FIGURE 18. AMERICAN OYSTERCATCHER CHICK SURVIVAL BY CLOSURE TYPE AT CAPE HATTERAS NATIONAL SEASHORE, 1999–2008**

Direct mortality of oystercatcher chicks from vehicles has been documented since 1995, when three chicks were found crushed in a set of vehicle tracks at the Seashore (Simons and Schulte 2008). Similar events have been documented at neighboring Cape Lookout National Seashore, where studies documented five chick deaths related to vehicles in 1995 (Davis et al. 1999), and one chick and two clutches lost in 1997 when they were run over by vehicles (Davis et al. 2001). Three oystercatcher chicks were killed during the 2003 and 2004 breeding seasons at Cape Hatteras by being run over by vehicles (NPS 2004f, 2005e), as documented by Seashore resource protection staff. A recent radio telemetry study conducted at Cape Hatteras and Cape Lookout national seashores identified human activity as the source of 16% of known chick mortality from 2005 through 2007 (Simons and Schulte 2008), with 8% of that related to vehicle collisions and 8% to other human disturbance.

**Weather and Tides.** Nine named hurricanes have affected the Outer Banks between 1993 and 2009 (NOAA 2009). Storms and associated high tides during breeding season can reduce nesting success. Overwash and other weather-related events accounted for 29% of documented nest failures at Cape Hatteras from 1999 through 2008. However, periodic hurricanes (outside the breeding season) can benefit oystercatcher nesting success in the long term through the creation of new habitat and the reduction of predators. For example, on Cape Lookout National Seashore, nests lost to predators dropped significantly after Hurricane Isabel flooded the island in September 2003. This drop was attributed to the reduction of the predator population due to hurricane-related flooding (Simons and Schulte 2008).

**Predation.** Numerous studies and reports have identified nest predation as a major source of oystercatcher nest failure (Davis et al. 2001; Sabine et al. 2006; McGowan et al. 2005; McGowan 2004;

Hodgson et al. 2008; Traut et al. 2006; Wilke et al. 2007). Mammalian predation was the major identifiable cause of nest failure for study sites in North Carolina from 1998 through 2008 (Simons and Shulte 2008). Predators include gray fox, red fox, raccoon, mink, dogs, cats, American crows, and gulls (Nol and Humphrey 1994). More recently, video nest recordings have documented raccoon, bobcat (*Lynx rufus*), and ghost crab predation of oystercatcher eggs and chicks at Cumberland Island National Seashore, Georgia (Sabine et al. 2006). Oystercatchers may lay another clutch if their eggs are lost or destroyed (Nol and Humphrey 1994).

As previously discussed, predation of oystercatchers is thought to be associated with human activities such as ORV use and pedestrian recreation (McGowan and Simons 2006; Simons and Schulte 2007; Sabine et al. 2008). McGowan and Simons (2006) hypothesized that human recreation might increase the activity of incubating oystercatchers, thereby leading to increased predation rates. Their research found a clear association between recreation and incubation behavior at Cape Hatteras and Cape Lookout during the 2002 and 2003 breeding seasons (McGowan and Simons 2006). The presence of ATV traffic was associated with increased numbers of trips parents made back and forth to nests and a decrease in duration of incubation. Recreational activities such as truck use and pedestrian traffic showed a weaker association with nesting behaviors, although the proximity of the disturbance to the nest was a factor. Evidence points to a reduction of nest success as the result of an alteration of incubation behavior due to recreational disturbance. McGowan and Simons (2006) hypothesized that mammals, which were found to be the main nest predators during this study (Davis et al. 2001), can better locate disturbed nests because adults leave a scent trail when going back and forth to nests. Human behavior and actions may also result in higher predator populations. For example, raccoon sightings and signs were greater in areas of increased human activity at Cape Lookout (Davis et al. 2001), and raccoon and bobcat signs appeared to be more abundant around areas of frequent human activity at Cumberland Island National Seashore, Georgia (Sabine et al. 2006).

In areas of frequent human activity, pedestrians were commonly observed in close proximity to nests, causing oystercatchers to leave their nests and exposing eggs and chicks to temperature extremes and greater risk of predators (Sabine et al. 2006).

## **COLONIAL WATERBIRDS**

Colonial waterbirds at the Seashore include gull-billed terns, common terns, least terns, and black skimmers. The listing status of each of these species at the state level is described below. None of these species is federally listed as threatened or endangered.

Ground-nesting colonial waterbirds breed along the Seashore beaches, which also host nesting sites for other birds, as well as a range of recreational activities for humans. Studies have documented that populations of some species of colonial waterbirds are declining. Beach nesters such as common terns, gull-billed terns, and black skimmers have shown the most significant declines. Coastal development, disturbances by humans, and increased nest predation all contribute to the decline in numbers of colonial waterbirds (NCWRC 2005).

## Colonial Waterbirds—Descriptions

### Gull-Billed Tern

The gull-billed tern is a medium-sized (13 to 15 inches long, weighing about 5.6 to 7.0 ounces), black-capped waterbird found widely in Eurasia, the Mediterranean, northern Europe, and the United States. In the United States, it occurs as two subspecies, with the Atlantic Coast and Gulf subspecies being designated *Sterna nilotica aranea* and the *S. n. vanrossemei* subspecies occurring from the Salton Sea in California south to western Mexico (Parnell et al. 1995). The gull-billed tern is listed on the USFWS 2008 Birds of Conservation Concern (USFWS 2008b) and is listed as threatened by the State of North Carolina.

**Gull-Billed Tern and Chick**

Credit: NPS

### Common Tern

The common tern can be found across the temperate region of the northern hemisphere. It also occurs in Bermuda and the southern Caribbean region (Nisbet 2002). It is one of the medium-sized, black-capped terns (12 to 14 inches long, weighing 3.8 to 5.1 ounces) (Nisbet 2002). In North America, it is distributed along the Atlantic Coast, the St. Lawrence River, and in most of the Great Lakes (Nisbet 2002). The common tern is listed on the USFWS 1995 list of Non-game Birds of Management Concern (USFWS 1995) and the 2008 Birds of Conservation Concern (USFWS 2008b), as well as being a North Carolina Species of Special Concern (NCWRC 2008b).

**Common Tern with Fish**

Credit: Phyllis Cooper / USFWS

### Least Tern

The least tern is the smallest of the black-capped terns in North America. Five races are recognized in North America, although there are few differences genetically or morphologically among them (Thompson et al. 1997). The least tern weighs only about 1.7 ounces, on average, and is only 8 to 9 inches in length (Thompson et al. 1997). The least tern is listed on the USFWS 1995 list of Non-game Birds of Management Concern (USFWS 2005) and the 2008 Birds of Conservation Concern (USFWS 2008b), as well as being a North Carolina Species of Special Concern (NCWRC 2008b).

Credit: NPS

### Black Skimmer

Black skimmers are the only waterbirds on the Atlantic Coast that feed by skimming along the surface of the water with their lower jaw. They are also unique in that males are on average 35% to 40% larger than females, and both exhibit a high degree of nocturnal behavior. Females average about 9.3 ounces and are 16 to 24 inches long, while males average about 13 ounces and are 19 to 24 inches long (Gochfeld and Burger 1994). The black skimmer is listed on

**Black Skimmer**

the USFWS 2008 Birds of Conservation Concern (USFWS 2008b), as well as being a North Carolina Species of Special Concern (NCWRC 2008b).

### Beach-Nesting Colonial Waterbirds in North Carolina

The Outer Banks region of North Carolina supports a large number of colonial waterbird species that depend upon its extensive sounds and the nearshore waters for feeding, and its relatively undisturbed islands for nesting. Most species of colonial waterbirds are in jeopardy in North Carolina (Parnell and Committee 1977) because of a decline in numbers over the past 20 to 30 years. During the period from 1977 to 2007, the number of gull-billed tern nests declined from approximately 268 to only 90, common tern nests from 2,761 to 498, and black skimmer nests from 976 to 555. The number of least tern nests, however, increased from 1,925 to 2,827 (NCWRC 2008b). Numbers of most breeding, colonial nesting shorebirds within North Carolina have declined over the past 20 to 30 years (Cohen et al. 2010; see table 29). For example, from 1977 to 2007, colonial waterbird nesting declined 30%, from 7,068 to 5,004 nests (table 29). Barrier island beaches provide important habitat for gull-billed terns, common terns, least terns, and black skimmers. Many of these beaches are severely degraded due to coastal development and associated increases in human disturbance and in predation by overabundant species. These factors have most likely contributed to the decline in colonial waterbird numbers in North Carolina (Cameron and Allen 2008).

**TABLE 29. NUMBERS OF COLONIAL WATERBIRD NESTS IN NORTH CAROLINA, 1977–2007**

Species	1977	1983	1988	1993	1995	1997	1999	2001	2004	2007	Average
Gull-billed tern	268	233	161	155	249	137	154	258	99	90	180.4
Common tern	2,761	2,247	2,618	2,122	1,699	952	888	1,131	570	498	1,548.6

### Descriptions of Breeding, Foraging, and Nonbreeding Habitats

#### Gull-Billed Tern

**Breeding Habitat.** Gull-billed terns typically nest among other tern and skimmer species on open, sandy shell beaches, on large barrier islands, on dredge-spoil islands, or on overwash fans (also used by piping plovers) that are mostly devoid of vegetation. They also nest on elevated-shell ridges (“rakes”) along the edges of marsh islands, which they share with American oystercatchers and common terns (Erwin et al. 1998; Cohen et al. 2010; Molina et al. 2009).

**Foraging Habitat.**

In contrast to other terns, gull-billed terns do not feed primarily on fish but are opportunistic, taking insects on the wing and feeding on a variety of invertebrates, including fiddler crabs (*Uca* spp.), decapods, marine worms, and clams, as well as small marsh fish (Cohen et al. 2010; Molina et al. 2009). Consequently, gull-billed terns can be seen feeding over marshes and creeks and along ocean and bay beaches, as well as over agricultural fields many miles from their nesting sites (Cohen et al. 2010; Molina et al. 2009).

**Nonbreeding Habitat.**

North American birds winter along the Gulf Coast, the Pacific Coast of Mexico, and into Central and South America. Little is known of gull-billed tern use of habitat while migrating, except that the habitat is generally considered

similar to nesting habitat (i.e., open beach, sand spits) (Cohen et al. 2010). Nonbreeding gull-billed terns can be found in coastal ponds, lagoons, mudflats, and flooded inland fields (Molina et al. 2009).

**Common Tern**

**Breeding Habitat.** Common terns typically nest on open, sandy shell beaches on ocean coastal islands, as well as at inland island sites in freshwater lakes, or, as in Europe, on rivers (Nisbet 2002). However, they also nest in saltmarshes, either on shell or on wrack, especially where human disturbance along the beaches is significant, and even on man-made structures, including large rooftops in urban areas (Erwin 1980).

**Foraging Habitat.** Common terns prey on small fish and shrimp in inlets and along the coast, often within a few miles of their breeding colonies. They are also known to feed on aquatic or terrestrial invertebrates such as crustaceans or insects (Nisbet 2002).

**Nonbreeding Habitat.** There is little information on habitats used by migrating common terns. However, most continue to feed close to shore. Migration staging areas are known at large sandy spits and bars at a number of North Atlantic sites, with concentrations numbering in the thousands at some places (Nisbet 2002). In winter, common terns migrate to the Caribbean and South America; both coasts of Africa; coasts and islands in the Indian Ocean; and the western Pacific from Japan to the Solomon Islands, New Guinea, and Australia (Nisbet 2002), where they often concentrate in large numbers in coastal lagoons (Nisbet 2002).

## Least Tern

**Breeding Habitat.** Least terns typically select the barest sand- and shell-covered substrates available on coastal, riverine, or dredge-spoil islands (Thompson et al. 1997). They also nest on rooftops in a number of coastal areas, where pea gravel is used as part of the roofing material (Thompson et al. 1997). On coastal barrier islands, they often select colony sites either adjacent to inlets or in overwash areas that are often interspersed among piping plover nests. Unlike common terns, least terns are typically found in small single-species colonies, where their nests are often widely spaced (Thompson et al. 1997). In New Jersey, inter-nest distance ranged from 2 to 66 meters (6 to 216 feet) at the time of egg laying and from 1 to 60 meters (3 to 197 feet) at the end of incubation (Burger and Gochfeld 1990).

**Foraging Habitat.** Least tern foraging habitat is similar to that of common terns, except that least terns seldom feed in large flocks.

**Nonbreeding Habitat.** Least terns migrate from the Outer Banks in August and September, with migration flocks staging at certain sandy island sites (Thompson et al. 1997). In late July or August, remote sandbars or sandy spits serve as roost sites. Least terns winter from Florida through the Caribbean and into Central and South America (Thompson et al. 1997).

## Black Skimmer

**Breeding Habitat.** Black skimmers prefer to nest on open, sandy substrates on barrier and dredge-spoil islands or at the tips of barrier islands (Gochfeld and Burger 1994). They invariably nest with other tern species along the Atlantic Coast (Erwin 1977; Cohen et al. 2010). Black skimmers occasionally nest on wrack or on shell ridges in saltmarshes and even on rooftops with least terns (Gochfeld and Burger 1994).

**Foraging Habitat.** Black skimmers feed on small fish, shrimp, and other invertebrates that they capture by skimming the surface with their lower jaws just below the surface of the water. They typically feed very close to their nesting colonies and prefer quiet waters in saltmarsh creeks, lagoons, or protected coves and inlets near barrier islands. The black skimmer is reportedly a nocturnal forager, but feeds regularly in daytime at the appropriate tide cycle, especially when feeding young (Erwin 1977; Cohen et al. 2010; Gochfeld and Burger 1994).

**Nonbreeding Habitat.** Black skimmers migrate from the Outer Banks region from September to November, forming very large concentrations on sandy spits and sandbars (Gochfeld and Burger 1994). They winter from Florida through the Caribbean and South America (Cohen et al. 2010; Gochfeld and Burger 1994).

## Breeding Biology

### Gull-Billed Tern

Birds arrive in North Carolina by mid-April. The mating system is monogamous, and like many other waterbirds, gull-bills probably have long-lasting pair bonds. Nest-site establishment and egg laying usually occur in mid- to late May. The nests consist of a shell-lined scrape in the sand or sometimes on wrack in saltmarshes. Nests contain from two to three brownish-blotched eggs (in the United States, the mean is around 2.2 eggs per nest [Molina et al. 2009]) that are incubated for 22 to 23 days. Members of a pair share incubation duties, but females take the dominant role. Gull-billed terns appear to be less tolerant of disturbance and less faithful to nest sites than other *Sterna* terns (Molina et al. 2009). Both parents share brooding duties, and both feed the young, often for an extended period after fledging occurs (birds generally fledge at 26 to 30 days of age). The chicks are highly camouflaged and more precocial

(mobile and independent) than either common tern or black skimmer chicks, with which they coexist. The young may leave the immediate area of the nest within a few days if disturbance is high. Pairs may re-nest if a nest is lost early in the breeding season (Cohen et al. 2010).

### **Common Tern**

Birds arrive in North Carolina in late April to early May and begin nesting most years from mid-May to early June (Nisbet 2002). The mating system is monogamous, and like many other waterbirds, common terns probably have long-lasting pair bonds. Clutch sizes vary, but three medium-dark-brown-mottled eggs are the norm. The eggs are incubated for 22 to 23 days. Both sexes incubate and feed the brood. As in other terns, feeding of the young occurs after fledging and can continue into the fall migration. Upon hatching, the young remain near the nest (unless disturbed) for the entire pre-fledging period. Re-nesting may occur if early nests fail. Fledging ranges from about 25 to 30 days. Common terns appear to serve as a social locus for mixed-species colony formation, possibly because of their aggressively protective nature (Erwin 1979; Cohen et al. 2010; Nisbet 2002). Hence, gull-billed terns and black skimmers often nest among common terns (Cohen et al. 2010).

### **Least Tern**

Birds arrive in North Carolina from late March to mid-April. Unlike most other Outer Banks terns, least terns usually nest in single-species colonies, with nests often spread far apart. Courtship lasts for two to three weeks in April and May, and egg laying occurs from late May until June. Clutch sizes range from one to three eggs, with two being the norm in North Carolina. Eggs are highly camouflaged, with the background color beige to light olive-brown. Members of a pair share incubation duties, but females take the dominant role. Incubation lasts for 21 to 22 days, and the highly mobile young move from the nest within a few days. They are able to fly at about 20 days of age. Post-fledging parental feeding can occur for several weeks away from the colony (Thompson et al. 1997; Cohen et al. 2010).

### **Black Skimmer**

Birds arrive in North Carolina from late April to mid-May, and nest building and egg laying usually occur from late May to mid-June (Erwin 1977; Cohen et al. 2010; Gochfeld and Burger 1994). Clutch sizes range from two to four eggs (Erwin 1977). Eggs are light buff with black blotches, and are laid and hatch at different times. Both sexes incubate the eggs, brood, and feed the young. Incubation ranges from 22 to 25 days. The young remain near the nest (unless disturbed) for most of the pre-fledging period of 28 to 30 days (Erwin 1977). As with other waterbirds, if nests fail early in the season, skimmers will re-nest (sometimes several times). Skimmers are sometimes seen incubating eggs as late as August in the mid-Atlantic region (Burger and Gochfeld 1990). Fledged young are fed by their parents, often right up until migration (Erwin 1977; Cohen et al. 2010). Human disturbance can seriously affect the breeding success of black skimmers (Gochfeld and Burger 1994). Pre-laying skimmers have been known to abandon a colony that is frequently disturbed (Erwin 1980; Safina and Burger 1983). Research has indicated that disturbed subcolonies of black skimmers had lower nest density, later nesting dates, and lower hatching and fledging success (Safina and Burger 1983).

### **Breeding Performance at Cape Hatteras National Seashore**

The beaches of the Seashore have been important in providing suitable habitat for these colonial nesters. In 2004, more than half of all nesting black skimmers and common terns in North Carolina were found at the Seashore, as well as one-third of the state's gull-billed terns (see tables 29 and 30).

Colonial waterbird breeding at Cape Hatteras generally occurs between the beginning of May and the middle of August. In many cases, colonial waterbirds use areas that were colonized in previous seasons, which include areas protected as prenesting closures for piping plovers. Colonies are commonly composed of small groups of least terns, but more diverse colonies sometimes occur.

Although different survey protocols have been used at the Seashore between 1977 and 2010, recent estimates of colonial waterbird nests at the Seashore are clearly much lower than they were 30 years ago (see table 30). Common terns, gull-billed terns, and black skimmers have shown the greatest declines over the last 30 years, both statewide and at the Seashore. These species are early nesters that require habitats of bare sand or shell with little or no vegetation for nesting. Historically, these species have nested primarily on barrier island beaches and have suffered declines most likely due to habitat loss and degradation (Cameron and Allen 2008). Other reasons for the decline in North Carolina's colonial waterbirds include mammal and bird predation, human development, beach stabilization, recreational disturbance, and perhaps, impacts on the wintering grounds (Parnell et al. 1995; Cohen et al. 2010). Recommended methods for colonial waterbird conservation include continued monitoring and management, habitat protection and restoration, predator management, and protection from human disturbance (Cameron and Allen 2008; Burger et al. 2004).

Within the Seashore, six gull-billed tern nests were recorded in 2007 on Green Island and none were found in 2008 or 2009, representing a decline from the Seashore's average of approximately 32 nests during surveys between 1977 and 2009. In 2010, one gull-billed tern nest was documented at Cape Point, but was lost before hatching. A total of 19 common tern nests were documented at the Seashore in 2008, although that number rose to 53 nests for the 2009 season and declined again in 2010 to 21 nests. The number of least tern nests rose dramatically at the Seashore in 2009, when 577 were documented by resource management staff. Black skimmer nest numbers have sharply declined at the Seashore, with only 11 nests in 2007 and 4 nests counted in 2008. However, 61 black skimmer nests were documented in 2009 (table 30). The number of nests recorded in 2007 for three of the four species was the lowest in the history of waterbird surveys in North Carolina (Cameron and Allen 2008). With the exception of the gull-billed tern, colonial waterbird numbers at the Seashore showed substantial increases during the 2009 breeding season (table 30).

**TABLE 30. NUMBERS OF COLONIAL WATERBIRD NESTS AT CAPE HATTERAS NATIONAL SEASHORE, 1977–2010**

Species	1977 <sup>a</sup>	1983 <sup>a</sup>	1988 <sup>a</sup>	1992 <sup>a</sup>	1993 <sup>a</sup>	1995	1997	1998	1999	2000	2001	2004 <sup>b</sup>	2007 <sup>b</sup>	2008	2009	2010	Avg.
Gull-billed tern	27	7	26	0	12	58	84	21	103	3	108	31	6	0	0	1	30.4
Common tern	802	763	678	278	422	503	718	715	440	129	573 <sup>c</sup>	376	109	19	53	21	412.4
Least tern	121	508	450	454	761	342	278	173	355	184	202	212	194	232	577	381 <sup>d</sup>	339

Source of 1977–2004 data is NPS 2007a

Source of 2007–2009 data is Muiznieks pers. comm. 2009 and NPS 2010g

Source of 2010 data is Muiznieks pers. comm. 2010d

<sup>a</sup> Surveys conducted by J. Parnell, University of North Carolina, Wilmington.

<sup>b</sup> Surveys conducted by NCWRC using non-NPS protocol.

<sup>c</sup> Updated from 2001 report to include nests found on Green Island at Oregon Inlet, which is now included in the Seashore boundary.

<sup>d</sup> The number of least terns recorded in 2010 is likely an underestimate, as there were 118 chicks on the ground in addition to the nests counted.

<sup>e</sup> The number of black skimmers recorded in 2010 is likely an underestimate, as there were 5 additional chicks on the ground that were counted during surveys for other species, after the survey window for black skimmers closed.

N/A = Not applicable.

## Nonbreeding

### Gull-Billed Tern

Fledged young and adults usually leave North Carolina's colonies by August, moving north for a short period before turning south for the fall and winter. Little is known of concentration areas during migration or winter, although wintering birds are known in Florida and the Gulf coastal region, from western Florida all the way south to Honduras and to Panama on the west coast. The gull-billed tern occasionally winters along the Atlantic Coast of North America as far north as North Carolina (Parnell et al. 1995; Cohen et al. 2010).

### Common Tern

Fledged young and adults usually leave North Carolina's colonies in late July to August. They often move north before staging at sandbars near inlets in September and then heading south. Little information is known about winter range, but they are known from Florida south through the Caribbean to Peru and southern Brazil, where tens of thousands have been recorded in late winter (Nisbet 2002).

### Least Tern

Fledged young and adults usually leave North Carolina's colonies in late July to August after breeding and also move northward into the New York to New England region before turning south to South America and the Caribbean. However, data are very limited on winter ranges (Thompson et al. 1997). Like other terns, least terns tend to congregate at staging areas along the Gulf Coast in August before departing for the winter (Thompson et al. 1997; Cohen et al. 2010).

### Black Skimmer

Fledged young and adults usually leave North Carolina's colonies by early August and disperse northward before heading south. Large flocks congregate at staging areas, often with terns. Adults may remain with their young during fall migration. Most birds from the mid-Atlantic region winter from southern North Carolina to Florida, the Caribbean, and into Central and South America (Gochfeld and Burger 1994; Cohen et al. 2010).

## Risk Factors

**Human Activity.** Ground-nesting colonial waterbirds are particularly vulnerable to impacts from human disturbance from ORVs, pedestrians, photographers, wildlife managers, and scientists because of the birds' usually high colony density and co-occurrence with human recreation (Erwin 1980; Cohen et al. 2010; Rodgers and Smith 1995; Rodgers and Schwikert 2002). Disturbances affect the birds' ability to feed, rest, and breed by evoking a flush response (Rodgers and Smith 1995; Rodgers and Schwikert 2002). Adverse effects from disturbance include egg and chick mortality, premature fledging, and reduced body mass (Rodgers and Smith 1995). Human activities that have indirect effects on bird behavior include sonic booms from military operations, aircraft disturbances, the presence of pets, and the leaving of garbage that subsequently attracts both avian and mammalian predators. Early in the spring, when the birds are first arriving and prospecting for breeding sites, even modest disturbances can be highly disruptive to colonial species (Buckley and Buckley 1976). Studies indicate that buffer distances between nesting areas and sources of human disturbances should be between 328 feet (100 meters) and 984 feet (300 meters), depending on the species and the particular behavior or reproductive stage (Rodgers and Smith 1995; Erwin 1989; Cohen et al. 2010). Recommended buffer distances from human disturbance are shown in table 31.

**TABLE 31. RECOMMENDED BUFFER DISTANCES FOR COLONIALY NESTING WATERBIRDS**

Species	Buffer Distance	Disturbance Type	Behavior/Stage	Source	Location
Mixed tern / skimmer colonies	591 feet (180 m)	Pedestrians and motor boats	Incubating and brooding adults	Rodgers and Smith 1995	Florida
Black skimmer	328 feet (100 m)	Pedestrian, ATV, ORV, boats	Adult foraging and loafing	Rodgers and Smith 1997	Florida
Least tern	328 feet (100 m)	All human disturbance	Established colonies post egg laying	Erwin 1989	Virginia, North Carolina
Common tern Black skimmer	656 feet (200 m)	All human disturbance	Established colonies, post egg laying	Erwin 1989	Virginia, North Carolina
Common tern Least tern	150 feet <sup>a</sup> (50 yds)	All human disturbance	Nesting	Blodget and Melvin 1996	Massachusetts
Common tern Least tern	300 feet (100 yds)	All human disturbance	Chicks	Blodget and Melvin 1996	Massachusetts
Least tern	656 feet (200 m)	All human disturbance	Courtship/nesting	Erwin 1989	Virginia, North Carolina
Common tern Black skimmer	984 feet (300 m)	All human disturbance	Courtship/nesting	Erwin 1989	Virginia, North Carolina
All colonial waterbirds	1000 feet (305 m)	All human disturbance	Established colonies	Buckley and Buckley 1976	New York New England
Least tern	328 feet (100 m)	All human disturbance	Buffer entire colony after nesting	Cohen et al. 2010	Cape Hatteras National Seashore
Black skimmer Common tern Gull-billed tern	200 m	All human disturbance	Buffer entire colony after nesting	Cohen et al. 2010	Cape Hatteras National Seashore
Least tern	282 feet (86 m)	Personal watercraft	Foraging and loafing	Rodgers and Schwikert 2002	Florida
Common terns	328 feet (100m)	Personal watercraft	Nesting	Burger 1998	New Jersey

<sup>a</sup> Buffer should be expanded as needed to prevent disturbance to incubating birds.

Human disturbance to waterbirds is frequently documented at the Seashore. At Cape Hatteras, four least tern chicks between ramps 23 and 30 and seven black skimmer chicks at Ocracoke Inlet were found dead or dying in ORV tracks during the 2003 breeding season. In all cases, the chicks were found adjacent to, but outside of, posted closures (NPS 2004g). Chicks become mobile after hatching, increasing their vulnerability. Colonial waterbird chick mortality from beach vehicles was documented every season from 2001 through 2004. Several chicks were killed by vehicles in 2001, 6 were killed in 2002, 11 were killed in 2003, and 6 were killed in 2004 (NPS 2002e, 2003b, 2004g, 2005d). Although no colonial waterbird deaths were directly attributed to impacts of human activity, instances of human disturbance to birds were reported in each colonial waterbird annual report from 2005 through 2009 (NPS 2006g, 2007g, 2008d, 2009k, 2010g). Although informational signs are posted around all resource closures (including those for colonial waterbirds), violations by pedestrians, ORVs, and dogs are common at the Seashore. In 2008 and 2009, there were several violations involving vehicles in colonial waterbird closures, including one that resulted in the crushing of a least tern egg by an ATV (NPS 2008h).

**Least Tern Egg Crushed by Unauthorized ATV Use**

**Weather and Tides.** Nine named hurricanes affected the Outer Banks between 1993 and 2009 (NOAA 2009). Flooding and high winds from storms can result in nest loss or failure, which was demonstrated in 1999 when Hurricane Dennis hit the North Carolina coast. Impacts from the hurricane flooded the entire Ocracoke Inlet colony, resulting in the loss of all chicks and eggs (NPS 2000c). Winter storms can also impact shorebirds. High mortality of many coastal bird species was noted after a snowstorm swept the entire North Carolina coast in 1989 (USFWS 1996a). Storms can also result in beneficial impacts to shorebirds, as seen in 2003 when Hurricane Isabel's passing resulted in the creation of a great deal of suitable beach nesting habitat (NPS 2004g).

**Predation.** Resource Management staff at the Seashore is of the opinion that the leading cause of colonial waterbird nest and brood failure is predation (NPS 2009k). Predators of colonial waterbirds include red fox, gray fox, mink, opossum, dogs, cats, American crows, gulls, and raccoon. Foxes, raccoons, opossum, and feral cats have increased in recent years as human populations have grown in coastal regions (Buckley and Buckley 1976; Erwin et al. 2001; Cohen et al. 2010). The result of this predation has been poor reproduction or major redistributions of species such as gull-billed terns, common terns, least terns, and black skimmers (Erwin et al. 2001, 2003; Cohen et al. 2010). In addition, gulls are often predators of terns (Nisbet 2002). These include great black-backed gulls (*Larus marinus*), herring gulls (*Larus argentatus*), and the smaller laughing gulls (*Leucophaeus atricilla*). In addition, in certain areas other bird species may prey on terns and skimmers (or their eggs), such as peregrine falcons (*Falco peregrinus*), great-horned owls (*Bubo virginianus*), fish crows (*Corvus ossifragus*), and others (Cohen et al. 2010). In 2008, the Seashore modified the existing predator trapping program to provide a more sustained trapping effort than occurred in previous seasons. The trapping program focused on depredation in the vicinity of shorebird nesting areas in an effort to reduce localized populations of raccoons, opossums, feral cats, red and gray foxes, and mink, which are all known predators of colonial waterbirds. However, raccoons at the Cape Point colony and mink at the South Ocracoke colonies severely hampered waterbird nesting success in those areas during the 2008 season (NPS 2009k).

## WILSON'S PLOVER

Wilson's plover is a medium-sized, ringed plover of coastal habitats. Its overall length is 6.5 to 7.5 inches, and its weight ranges between 2 and 2.5 ounces. At all times of the year and in all plumages, its bill is entirely black, large, and heavy; its upperparts are generally grayish to grayish brown, and its underparts are white, with a black-to-brownish breast-band. Its legs and feet are flesh-colored to pinkish. It is readily distinguished from other, similar, ringed plovers by its larger size; by its large, heavy, all-black bill; and by its flesh-colored legs. The piping plover is smaller than Wilson's plover, having obviously paler upperparts, orange legs, and a much smaller, stubbier, two-toned bill that has an orange-yellow base and a black tip (Corbat and Bergstrom 2000; Hayman et al. 1986; Howell and Webb 1995). Wilson's plover has no federal protection status in the United States; however, it was classified as a species of conservation concern by the USFWS in 2002. Birds that appear on this list are those that, without additional conservation actions, are likely to become candidates for listing under the ESA (USFWS 2002; 16 USC 1531–1544). Brown et al. (2001) list Wilson's plover as a species of high concern in their prioritization of shorebird species according to relative conservation status and risk. Wilson's plover is listed as endangered in Virginia and Maryland, threatened in South Carolina, rare in Georgia, state protected in Alabama (Corbat and Bergstrom 2000), and as a species of special concern in North Carolina (15A NCAC 101.0105).

**Wilson's Plover**

Credit: Terry Hartley / Due South Photography

### Distribution

**Breeding.** Wilson's plover is distributed locally along the Atlantic Coast, from Virginia south to southern Florida, including the Florida Keys, and from southern Florida west along the Gulf Coast to Veracruz, Mexico, the Yucatán, and Belize (Stevenson and Anderson 1994). Breeding locations are uncertain farther south along the Caribbean Coast of Central America.

In South America, Wilson's plover breeds locally along the Atlantic Coast, from Colombia south to Brazil, and includes the islands of Trinidad, Aruba, Bonaire, Margarita, and Curaçao, located off the coast of Venezuela (Meyer de Schauensee and Phelps 1978). In the West Indies, it breeds throughout the Bahamas, the Greater Antilles, the Virgin Islands, the Lesser Antilles, and in the Grenadines (Raffaele et al. 1998).

Along the Pacific Coast, Wilson's plover breeds locally along the west coast of Baja California, and from the Gulf of California south to Nayarit, Mexico (Howell and Webb 1995). Farther south along the Pacific Coast, it breeds from Mexico to Ecuador and Peru (Hilty and Brown 1986).

**Wilson's Plover Chick**

Credit: NPS

**Nonbreeding.** Wintering occurs mainly in northeast and central Florida (Corbat and Bergstrom 2000), as well as in west Louisiana and south Texas throughout the remainder of the breeding range (see above), to northern South America (Hayman et al. 1986).

### **Wilson's Plover in North Carolina and at Cape Hatteras National Seashore**

A 2004 survey of the entire coast of North Carolina yielded 232 pairs of Wilson's plover. Of those, the Seashore supported two pairs of Wilson's plover on Ocracoke Island. In contrast, in 2004, Cape Lookout National Seashore supported 61 pairs and two individuals, which represented 26% of North Carolina's population of Wilson's plover (Cameron pers. comm. 2005). Wilson's plovers are often seen by Seashore staff during their piping plover observations, but no indications of nesting had been documented until 2009 when a three-egg nest was found in June. The nest hatched in July and produced one chick. The chick was not observed during subsequent observations and is not believed to have fledged (Muiznieks pers. comm. 2009). During the 2010 breeding season, two nests were documented on Ocracoke Island. One of these nests successfully fledged two chicks (Muiznieks pers. comm. 2010d).

More comprehensive surveying of wintering shorebirds is being conducted per the NPS SECN Winter Monitoring Program. Implementation of the SECN Migratory, Wintering, and Beached Shorebird Monitoring Protocol at Cape Hatteras began in mid-July 2006. Only a few Wilson's plovers were observed at the Seashore from July to early December, and all birds were seen in foreshore habitat at low tide. SECN staff attributed the low numbers to insufficient training of field staff on the proper identification of Wilson's plover (Byrne et al. 2009). Seashore staff has not completed a comprehensive survey of nonbreeding Wilson's plovers, so it is not known if the Seashore supports wintering populations.

Wilson's plover is listed on the USFWS 1995 list of Non-game Birds of Management Concern (USFWS 1995) and the 2008 Birds of Conservation Concern (USFWS 2008b), and is a North Carolina Species of Special Concern (NCWRC 2008b).

### **Habitat Description**

Wilson's plovers are typically associated with coastal areas of high salinity and sparse vegetation, including salt flats, coastal lagoons, sand dunes, foredunes, and overwash areas above the high-tide line (Tomkins 1944; Hayman et al. 1986; Corbat and Bergstrom 2000). At the Seashore, Wilson's plover breeding sites have only been known to occur within piping plover closures. Hence, all closures, and much of the management of piping plovers, also apply indirectly to Wilson's plover.

### **Diet**

Wilson's plover is a visual feeder on crustaceans, particularly fiddler crabs, and some insects (Strauch and Abele 1979; Morrier and McNeil 1991; Thibault and McNeil 1994), which they prey upon at intertidal mudflats, sand flats, ephemeral pools, and shores of brackish ponds. They usually forage at low tide on intertidal mudflats (Strauch and Abele 1979; Thibault and McNeil 1994; Corbat and Bergstrom 2000).

### **Breeding Biology**

Before territories are established in mid-March to early April (Tomkins 1944; Corbat and Bergstrom 2000), Wilson's plovers form pairs, and most breeding territories are established by mid-April. As with the piping plover, the nest is a scrape in sand that requires little construction (Bergstrom 1988). Egg laying peaks from late April through late May (Bergstrom 1988). Re-nesting after failure of a first nest

can continue through the end of June. The estimated time required to complete a clutch of three eggs is four to six days (Bergstrom 1988; Corbat and Bergstrom 2000).

### **Reproductive Success at Cape Hatteras National Seashore**

The first documented Wilson's plover nest was found in 2009. A three-egg nest was found in June, hatched in July, and produced one chick. The chick was not observed during subsequent observations and is not believed to have fledged (Muiznieks pers. comm. 2009). During the 2010 breeding season, two nests were documented on Ocracoke Island. One of these nests successfully fledged two chicks (Muiznieks pers. comm. 2010d).

### **Risk Factors**

Because Wilson's plovers commonly nest on beaches with wide berms, which are also favored by birds like piping plovers, Wilson's plovers are subject to disturbances at their nests and roosts by the same factors as those that affect the piping plover, including beachgoers, pets, and ORV traffic on beaches. Wilson's plovers leave their nests when disturbed and are extremely reluctant to return when intruders are anywhere near, a practice that exposes eggs to predation and overheating (Corbat and Bergstrom 2000).

### **RED KNOT**

The red knot is a shorebird that breeds in the Canadian Arctic and is known to visit North Carolina, the Outer Banks, and the Seashore, as well as the entire eastern seaboard of the United States, only as a migrant and an occasional winter resident (Harrington 2001). There are five subspecies currently recognized (*Calidris canutus canutus*, *C.c. rufa*, *C.c. islandica*, *C.c. rogersi*, *C.c. roselaari*) (Harrington 2001). Two of these (*C.c. rufa* and *C.c. roselaari*) are found in the United States but only during migration and in the winter. Southward migration of *C.c. rufa* and *C.c. roselaari* begins in mid-July, with staging occurring along the United States Atlantic Coast (Harrington 2001). Only those aspects of the red knot's life pertinent to its management and conservation in North Carolina, the Outer Banks, and the Seashore are covered in this section. The red knot is not listed as threatened or endangered by the USFWS, but it is a federal candidate species. The red knot does not carry state status in North Carolina.

### **Emergency Endangered Listing and Taxonomy**

On August 1, 2005, in response to the 80% decline in red knot population over the past 10 years, leading conservation groups filed an emergency petition asking the USFWS to list the red knot as an endangered species under the ESA. The listing request came from an alliance of wildlife groups, including Defenders of Wildlife, New Jersey Audubon Society, American Bird Conservancy, the National Audubon Society, Delaware Audubon Society, Citizens Campaign for the Environment, Audubon New York, Audubon Maryland–DC, and the Virginia Audubon Council. On September 12, 2006, the USFWS announced that it had designated the red knot as a candidate for ESA protection. On February 27, 2008, conservation groups again petitioned the Department of the Interior to list as endangered the *rufa* subspecies of the red knot, and a broader taxon comprising both the *rufa* subspecies and the *roselaari* subspecies.

**Red Knot**  
Credit: USFWS

Another indication of conservation concern for the red knot is the fact that in August 2004, the U.S. Fish and Wildlife Service published its list of U.S. and Canadian shorebird populations that are considered highly imperiled or of high conservation concern (USFWS 2004c). The Canadian Arctic–Atlantic Coast population of the red knot was one of eight taxa classified as Highly Imperiled. In 2008, the USFWS, which proposes candidates for listing under the ESA, determined that the ranking for the red knot should be raised from 6 to 3. The species' listing priority dictates the relative order in which proposed listing rules are prepared, with the species at greatest risk (listing priority 1 through 3) being proposed first (American Bird Conservancy 2008).

## Description

The red knot is characteristically found along the east coast of the United States, with its greatest population staging on Delaware Bay (Tsipoura and Burger 1999) on its migration from its breeding ground in the Canadian Arctic to the Tierra del Fuego region of Chile and Argentina in South America. It is this subspecies that is the subject of the emergency petition.

Males in breeding plumage have a dark red or salmon breast, throat, and flanks, with a white belly. Their crowns and backs are flecked with gray and salmon (Harrington 1996, 2001; Paulson 1993). Female coloration is similar to that of males but is typically less intense. Nonbreeding plumage is a plain gray on the head and back, with light fringes of gray and white along the wings, giving an appearance of a white line running the length of the wing when in flight. The breast is white, mottled with gray, and the belly is dull white. For both male and female, the bill is black (year-round), and the legs are dark gray to black (Harrington 1996, 2001). The average weight of the red knot is 5 ounces (which varies considerably through the year), with a body length between 9 and 10 inches.

## Range and Migration

Red knots are found in the Arctic regions of Canada during the breeding season, which is mid-June through mid-August. They winter from November to mid-February primarily in two separate areas in South America—Tierra del Fuego in Chile and Argentina, and in Maranhão, northern Brazil (American Bird Conservancy 2005). Additional, smaller numbers of red knots also winter farther northwest in French Guiana and in the coastal, southeastern United States, including North Carolina, the Outer Banks, and the Seashore.

Red knots have one of the longest migrations of any shorebirds. Those individuals that winter in southern South America embark on their northern migration in February, with peak numbers leaving Argentina and southern Chile in mid-March to mid-April (Harrington 1996, 2001). The first stopover is along the coast of southern Brazil (Vooren and Chiaradia 1990), and the final stopover is the Delaware Bay. Their southward migration from the Canadian Arctic begins in mid-July. They arrive in South America along the coast of the Guianas in mid- to late August (Spaans 1978). From the Guianas, red knots continue to move southward along the Atlantic coastline of South America, and the greater part of the population will continue on to Tierra del Fuego to winter (Morrison et al. 2004).

These long-distance migrations can only occur when the birds have access to productive refueling stops, particularly on their northern migrations, which involve fewer stops than the southern ones. For red knots on the eastern seaboard of the United States, Delaware Bay is the most crucial spring stopover because it is the primary final stop at which the birds can refuel in preparation for their nonstop leg to the Arctic.

When they arrive at their final destination, weather conditions can be harsh, and food is scarce. Their fat reserves from the Delaware Bay must sustain them not only during their 2,400-kilometer (1,488-mile) final flight, but also upon arrival in the Arctic until food resources become more plentiful (Baker et al. 2004).

Red knots do not breed at the Seashore, but use it in the winter and during spring and fall migration.

### **Nonbreeding Habitat**

Harrington (1996, 2001) describes how, during the winter, the red knot frequents intertidal habitats, notably along ocean coasts and large bays. Both areas usually display high waves or strong currents while supplying a sandy habitat. These areas are selectively chosen in South America, with the most abundant population on the island of Tierra del Fuego in Argentina and Chile (Morrison and Ross 1989).

On migration, the red knot principally uses marine habitats in both North and South America. Coastal habitats along the mouths of bays and estuaries are preferred, providing sandy beaches on which to forage (Harrington 1996, 2001). Niles et al. (2007) suggested that red knots consistently use coastal areas of North Carolina during spring and fall migration and indicated that approximately 1,000 red knots were observed on Ocracoke Island in early May 2005. Red knots are also known to use tidal flats in more sheltered bays or lagoons in search of benthic invertebrates or horseshoe crab eggs (Harrington 1996, 2001; Tsipoura and Burger 1999). In some cases, beach habitats are preferred because of high densities of benthic bivalves (Harrington 1996). Red knots also use tidal flats in more sheltered bays or lagoons, where they hunt for benthic invertebrates (Harrington 2001) or for special foods, such as horseshoe crab eggs (Harrington 1996; Tsipoura and Burger 1999). Delaware Bay hosts the largest number of spawning horseshoe crabs (a primary food source for the red knot) in the United States. At Delaware Bay, the red knots feed and put on weight needed for winter migration. The increasing human harvest of the horseshoe crab has reduced this food source for red knots, and this dearth is believed to be contributing to the red knot's failure to reach its needed threshold departure weight of 6.3 to 7.0 ounces. Hence, there has been a systematic reduction in the body weight of red knots leaving Delaware Bay for the Arctic, which negatively impacts their ability to survive and breed (Baker et al. 2004). Since 1999, reductions in commercial harvesting of horseshoe crabs in New Jersey and Delaware have been substantial, although the effect on horseshoe crab populations is not yet known. Preliminary 2009 information indicated that red knots were able to attain threshold departure weights and left the Delaware Bay stopover in good condition. However, it remains to be seen if this will become a long-term trend (FR 2009).

### **Nonbreeding Observations at Cape Hatteras National Seashore**

During their wintering shorebird study, SECN staff observed red knots at the Seashore from August 2006 through February 2007. Monthly counts were highly variable with the two highest single-day counts in November 2006 and February 2007. Almost all red knots documented during this time were located in the foreshore habitat type (Byrne et al. 2009). When the Seashore took over monitoring from SECN staff, only the points and spits were surveyed to meet the migratory and wintering piping plover survey requirements of the USFWS biological opinion. At that time limited staffing in the winter months prohibited more extensive surveys. As the result of additional full-time staffing in the early part of 2010, resource management staff began surveying the entire shoreline for red knots along with other shorebirds on March 18, 2010. The protocol was revised to accommodate the increased staffing level and will provide a more comprehensive, standardized approach for determining use of the shoreline by selected shorebirds.

## Risks

Red knots are highly vulnerable to degradation of the resources on which they depend to accomplish their migrations. Morrison et al. (2004) have identified four factors that cause this vulnerability: (1) a tendency to concentrate in a limited number of locations during migration and on the wintering grounds so that deleterious changes can affect a large proportion of the population at once; (2) a limited reproductive output, subject to vagaries of weather and predator cycles in the Arctic, which, in conjunction with a long lifespan, suggests slow recovery from population declines; (3) a migration schedule closely timed to seasonally abundant food resources, such as horseshoe crab eggs during spring migration in Delaware Bay (Tsipoura and Burger 1999), suggesting that there may be limited flexibility in migration routes or schedules; and (4) occupation and use of coastal wetland habitats that are affected by a wide variety of human activities and developments (Bildstein et al. 1991).

## WILDLIFE AND WILDLIFE HABITATS

In addition to the federally listed threatened or endangered species and other protected species detailed in previous sections of this chapter, other wildlife species depend on the habitats within the Seashore. This section describes those invertebrate species and other bird species that could be found

in the study area and could be affected by ORV management alternatives.

## OTHER BIRD SPECIES

The Outer Banks of North Carolina provide a critical link in the migratory path of several shorebird species. The barrier island ecosystems at the Seashore provide habitat for large numbers of migratory and nesting bird species, and coastal marshes are critical to wintering populations of many waterbirds. Nearly 400 species of birds have been sighted within the Seashore and its surrounding waters (Fussell et al. 1990). Migration routes for many raptor species include southeastern barrier islands.

Thousands of migrating shorebirds use the barrier islands as a stopover point to rest, forage, or spend the winter (Manning 2004). In 1999, the American Bird Conservancy designated Cape

Hatteras National Seashore as a Globally Important Bird Area in recognition of the Seashore's value in bird migration, breeding, and wintering (American Bird Conservancy 2005).

**Marbled Godwit**

Credit: Lee Karney / USFWS

Studies have recorded 21 species of shorebirds (table 32) on the beaches of the Outer Banks of North Carolina, such as whimbrels (*Numenius phaeopus*), willets (*Catoptrophorus semipalmatus*), and sanderlings (*Calidris alba*). These shorebirds are most abundant in May and August. Least terns, common terns, gull-billed terns, black skimmers, piping plovers, Wilson's plovers, willets, and American oystercatchers can all be found nesting on North Carolina beaches (North Carolina Audubon 2008). Several of these species are designated as state-listed and/or federally listed threatened or endangered

species and are discussed in a previous section of this chapter. However, nonlisted shorebirds such as willets have similar nesting and foraging habitats to those of state- and federally listed species. The eastern willet, for instance, breeds in coastal saltmarshes and nests on the ground, often in colonies, usually in well-hidden locations in short grass. These birds forage on mudflats or in shallow water, probing or picking up food by sight. Their diet consists of insects, crustaceans, and marine worms, as well as some plant material. Although not state-listed or federally listed, several of the shorebirds found at the Seashore appear on the USFWS Birds of Conservation Concern list, which identifies migratory birds that, without additional conservation actions, are likely to become candidates for listing under the ESA (USFWS 2008b). Other waterbirds found at the Seashore include gulls, pelicans (*Pelecanus* spp.), terns, and egrets (family Ardeidae) (NCWRC 2005).

**TABLE 32. SHOREBIRDS ON THE OUTER BANKS OF NORTH CAROLINA, 1992–1993**

Scientific Name	Common Name
<i>Pluvialis squatarola</i>	Black-bellied plover
<i>Charadrius wilsonia</i>	Wilson's plover
<i>Charadrius semipalmatus</i>	Semipalmated plover
<i>Charadrius melodus</i>	Piping plover
<i>Haematopus palliatus</i>	American oystercatcher
<i>Catoptrophorus semipalmatus</i>	Willet
<i>Numenius phaeopus</i>	Whimbrel
<i>Limosa fedoa</i>	Marbled godwit
<i>Arenaria interpres</i>	Ruddy turnstone
<i>Calidris canutus</i>	Red knot
<i>Calidris alba</i>	Sanderling
<i>Calidris pusilla</i>	Semipalmated sandpiper
<i>Calidris mauri</i>	Western sandpiper
<i>Calidris minutilla</i>	Least sandpiper
<i>Calidris alpina</i>	Dunlin
<i>Limnodromus griseus</i>	Short-billed dowitcher
<i>Charadrius vociferous</i>	Killdeer
<i>Tringa melanoleuca</i>	Greater yellowlegs
<i>Tringa flavipes</i>	Lesser yellowlegs
<i>Actitis macularia</i>	Spotted sandpiper
<i>Calidris fuscicollis</i>	White-rumped sandpiper

Source: Dinsmore et al. 1998

Migratory birds are often found at the Seashore throughout the year. During the winter months, the common loon (*Gavia immer*), pied-billed grebe (*Podilymbus podiceps*), northern gannet (*Morus bassanus*), tundra swan (*Cygnus columbianus*), and Canada goose (*Branta canadensis*) are common sights at the Seashore. During the summer migratory season, several varieties of herons (*Ardea* spp.), Audubon's shearwater (*Puffinus lherminieri*), and the barn swallow (*Hirundo rustica*) populate the Cape Hatteras shores. While less frequently sighted, grebes (*Podiceps auritus*), mallard ducks (*Anas*

*platyrhynchos*), hawks (genus *Accipiter*), bald eagles (*Haliaeetus leucocephalus*), peregrine falcons, and various species of sandpipers also inhabit the Seashore at one point or another throughout the year. Studies have demonstrated the importance of the Outer Banks as a staging area for piping plovers, whimbrels, and sanderlings when compared to other areas along the Atlantic Coast and confirmed that the area provides a critical link in the migratory path of several shorebird species (Dinsmore et al. 1998).

## INVERTEBRATES

The Seashore beach ecosystem is home to a vast quantity of invertebrates, which form a valuable link in the coastal food chain. Many of the protected bird species found within the Seashore, including the piping plover, Wilson's plover, red knot, American oystercatcher, and gull-billed tern, feed on invertebrates in areas that are open to ORV use, such as the intertidal zone and the wrack line. High-energy, intertidal beaches in the southeastern United States generally support approximately 20 to 30 types of invertebrate species (Ruppert and Fox 1988), with the most identifiable being mole crabs, ghost crabs, and coquina clams (*Donax variabilis*). Both mole crabs and coquina clams are a primary prey base for fish, crabs, and shorebirds, and the population density of some predators may actually be dependent on the availability these invertebrate species (Greene 2002). Other invertebrates within the Seashore beach ecosystem include clamworms (*Nereis succinea*), limpets (*Patella vulgata*), which can be found in the intertidal zone, and varieties of jellyfish sea urchins and sea stars (class Asteroidea), all of which spend their entire lives in the water.

**Ghost Crab**

Credit: George Harrison / USFWS

Ghost crabs are sand-colored, terrestrial animals with square-shaped bodies, which are generally no more than 2 to 3 inches wide (Lippson and Lippson 1997). Ghost crabs are a top predator of the beach ecosystem and can be used as an indicator species to analyze the health of the beach ecosystem due to their prominence and high susceptibility to anthropogenic disturbances (Hobbs et al. 2008). They are primarily nocturnal and create burrows for shelter from heat and desiccation (drying) stress during the warmer afternoon periods. Burrows are usually 0.6 to 1.2 meters in length and are generally located in an area from the high-tide line landward up to 400 meters.

Ghost crabs emerge from their burrows at night to feed in the intertidal zone, and travel up to 300 meters while foraging (Hobbs et al. 2008). Ghost crabs retreat deep into their burrows during the winter months (Lippson and Lippson 1997).

Like ghost crabs, mole crabs are a common inhabitant of the high-energy, exposed beach environment. In contrast to other species of crabs, they do not have claws or pincers. Mole crabs are generally less than 2 inches in length and have egg-shaped bodies that allow for rapid digging in wet sand (Ruppert and Fox 1988). Mole crabs are filter feeders that burrow and anchor themselves into the sands within the swash zone, collecting organic matter that they trap within their feeding antennae when water recedes over the buried crabs. Unlike ghost crabs, mole crabs move off the beach to deeper offshore waters during the winter (Lippson and Lippson 1997).

Marine bivalves such as oysters (*Crassostrea virginica*), razor clams, coquina clams, and ribbed mussels (*Geukensia demissa*) also inhabit the Seashore, forming the diet for many birds. Clams characteristically lie buried just beneath the surface of the sand, although they can burrow to greater depths as necessary. Much like the mole crab, coquina clams are filter feeders and migrate up and down the ocean beach in the intertidal area during the spring and summer (Ruppert and Fox 1988). Due to its importance in food webs, the coquina clam is considered an indicator species for the sandy beach oceanfront habitat. It feeds on

small particles such as unicellular algae and detritus and in turn, is consumed by fish and birds (SCDNR 2009).

In addition to the intertidal zone, another important habitat for invertebrates is the wrack line. A wrack line is a line of stranded debris along a beach face marking the point of maximum run-up during a previous high tide. The wrack line is often composed of drying seaweed, tidal marsh plant debris, decaying marine animals, shells, and miscellaneous debris washed up and deposited on the beach. The wrack line provides a habitat suitable for many invertebrates such as amphipods, beetles, mites, flies, and spiders. Studies have demonstrated that ORV use in and around the wrack line reduces the density of invertebrates in beach environments.

**Intertidal Zone**

Credit: NPS

A 3-year study on Cape Cod and Fire Island, New York (Kluft and Ginsberg 2009), found that the shrimp-like crustaceans called amphipods are particularly vulnerable to drying out in immature stages, and use the wrack line as cover. Several species of flies also use the site to lay their eggs, and wolf spiders (family Lycosidae) migrate back and forth from the beach grass to the wrack line to feed on these amphipods. The study observed that higher ORV traffic resulted in dispersal and desiccation of the wrack line, thereby reducing the populations of invertebrates in these areas.

## SOUNDSCAPES

According to the NPS, the acoustical environment is comprised of a combination of acoustic resources, including natural, cultural, and historical sounds. A soundscape is defined as the way in which humans perceive this acoustic environment (NPS 2009g). Specifically, the natural soundscape encompass all of the natural sounds that occur in parks, including the physical capacity for transmitting those natural sounds and the interrelationships among park natural sounds of different frequencies and volumes (NPS *Management Policies 2006* [NPS 2006c, sec 4.9]). Natural sounds may range from bird and bat calls and insect chirps, to sounds produced by physical processes like wind rushing through leaves on trees, thunder, and rushing and falling water through rivers, creeks and streams within a park. According to the NPS, 72% of visitors indicate that a crucial reason for the need to preserve national parks is that parks provide opportunities to experience natural peace and the sound of nature (NPS 2009g). Therefore, the NPS works to preserve, to the greatest extent possible, the natural soundscapes of parks.

## NOISE FUNDAMENTALS

According to the NPS, “although noise has been used as a synonym for sound, it is essentially the negative evaluation of sound by people, is extraneous, or undesired. Humans perceive sound as an auditory sensation created by pressure variations that move through a medium such as water or air and is measured in terms of amplitude and frequency” (NPS 2009g). Sources of noise within national parks are dependent upon the particular park and may include vehicular sources (cars, buses, or other vehicles) used for tours and access to trails and campgrounds, aircraft overflights from planes, helicopters and military jets along with airport development, snowmobiles and watercraft, park operations and energy development (NPS 2009i).

The magnitude of noise is usually described by its sound pressure. Since the range of sound pressure varies greatly, a logarithmic scale is used to relate sound pressures to some common reference level, usually the decibel (dB). Sound pressures described in decibels are called sound pressure levels and are often defined in terms of frequency-weighted scales (A, B, C, or D).

The A-weighted decibel scale is commonly used to describe noise levels because it reflects the frequency range to which the human ear is most sensitive (1,000–5,000 Hertz) (Caltrans 1998). Sound levels measured using an A-weighted decibel scale are generally expressed as dBA. Throughout this section, all noise levels are expressed in dBA. Several examples of sound pressure levels in the A-weighted (dBA) scale are listed in table 33, while table 34 presents examples of sound pressure levels measured in national parks.

**TABLE 33. EXAMPLES OF COMMON SOUNDS**

A-weighted Sound Level (dBA)	Overall Level	Noise Environment
120	Uncomfortably loud (32 times as loud as 70 dBA)	Military jet airplane takeoff at 50 feet
100	Very loud (8 times as loud as 70 dBA)	Jet flyover at 1,000 feet Locomotive pass-by at 100 feet
80	Loud (2 times as loud as 70 dBA)	Propeller plane flyover at 1,000 feet. Diesel truck 40 mph at 50 feet
70	Moderately loud	Freeway at 50 feet from pavement edge at 10:00 a.m. Vacuum cleaner (indoor)
60	Relatively quiet (one-half as loud as 70 dBA)	Air condition unit at 100 feet. Dishwasher at 10 feet (indoor)
50	Quiet (1/4 as loud as 70 dBA)	Large transformers Small private office (indoor)
40	Very quiet (1/8 as loud as 70 dBA)	Birds calls. Lowest limit of urban ambient sound
10	Extremely quiet	Just audible (1/64 as loud as 70 dBA)
0	Threshold of hearing	Quietest sound detectible by a healthy human ear

## HUMAN AND WILDLIFE RESPONSE TO CHANGES IN NOISE LEVELS

Noise may have adverse effects on the human population in a variety of ways. Noise may interfere with human activities, such as sleep, speech communication, and tasks requiring concentration or coordination. At a physiological level, noise may also cause annoyance, hearing damage, and other health-related problems. The degree of disturbance from unwanted sound depends essentially on (1) the amount and nature of the intruding noise; and (2) the type of activity occurring where the noise is heard. In considering the first of these factors, it is important to note that individuals have different sensitivity to noise. Loud noises bother some people more than others, and some patterns of noise also affect a person's perception of whether or not a noise is offensive. With regard to the second factor, individuals tend to judge the annoyance of noise relative to the natural sounds (i.e., without the intruding noise source) and activities occurring where the noise is heard. For example, if regions of a park are dedicated to enjoying the tranquility and serenity of the natural environment, sounds from motor boating and hunting would be distracting to the visitor experience. However, if these activities are consistent with the purpose of a particular region of the park, these sounds would be considered appropriate. Therefore, noise is a subjective term, and it is important to characterize the activities essential to the park's purpose (NPS 2000a).

It is widely accepted that the average healthy ear can barely perceive noise level changes of 3 dBA or less. A change of 5 dBA is readily perceptible and an increase or decrease of 10 dBA is perceived as being twice or half as loud, respectively (see table 35).

**TABLE 35. DECIBEL CHANGES, LOUDNESS AND ENERGY LOSS**

Sound Level Change	Relative Loudness	Acoustic Energy Loss
0 dBA	Reference	0.0%
- 3 dBA	Barely perceptible change	50.0%
- 5 dBA	Readily perceptible change	67.0%
- 10 dBA	Half as loud	90.0%
- 20 dBA	1/4 as loud	99.0%
- 30 dBA	1/8 as loud	99.9%

Source: FHWA 1995

NOTE: This table underestimates changes in perceived loudness for low frequency noise, including transportation noise, which falls within the frequency range of 100 Hz to 1 kHz.

Wildlife is very sensitive to sound, as animals often depend on auditory cues for hunting, predator awareness, sexual communication, defense of territory, and habitat quality assessment (Barber et al. 2010). Negative population-level, behavioral, and habitat use consequences of higher ambient sound levels from human voices, along with sound events associated with human activities (motorists, snowmobiles, hikers), have been observed in many species (Frid and Dill 2002; Landon et al 2003; Habib et al. 2007).

Birds are especially susceptible to human-associated environmental sounds as they rely heavily on auditory cues for identifying and attracting suitable mates, pair bonding, communication among and detection of predator alerts or warning signals (Francis et al. 2009). Similar to physical degradation of the habitat caused by development or other human activities, the low frequency, high-amplitude, nearly

omnipresent sound produced by roads, vehicles, airports, and mechanical equipment has been found to result in a decline in species diversity, abundance, and breeding success (Rheindt 2003).

Researchers found that the presence of low-frequency mechanical noise limits communication between members of the same species, often reducing nesting success (Habib et al. 2007). For example, female zebra finches, exposed to high-amplitude, low-frequency sounds such as those produced by traffic or other motor vehicles, showed less preference for their pair-bonded male. As the amplitude of ambient, low-frequency sounds increased, the strength of pair bonds decreased. This type of behavior may reduce pairing success, disrupt the strength of sexual selection, and affect the overall genetic structure of a population of birds nesting and seeking mates in the vicinity of roadways or in other areas exposed to high-amplitude mechanical noise (Swaddle and Page 2007). Similarly, nesting shorebirds on Cape Hatteras using areas exposed to low-frequency sounds from ORVs or wheeled vehicles may exhibit all or some of these behaviors, which may change the genetic structure of a population, or limit parental care of young, resulting in decreased nesting success. Louder sounds (higher amplitude) have the greatest potential to adversely affect pair bonds of shorebirds, thus shorebirds using areas of heavier use or with more exposure to high amplitude sounds would be most likely to be affected.

The diversity of bird species and the population of many bird species decrease in locations closer to a road or other sources of mechanized sound, which is described as the 'road effect' (Francis et al. 2009). This effect is often attributed to mechanical noise levels rather than to decreased habitat quality or direct mortality caused by vehicle collisions (Reijnen et al. 1995; Rheindt 2003). On Cape Hatteras, road effects are likely to occur both near roads used by motorized vehicles, and along shorelines open to ORVs. Certain species suffer more negative effects than others. Researchers have found this is due, in part, to a greater difference between a bird's song frequency and the low-frequency sound produced by motorized vehicles. That is, birds with higher-frequency songs may have greater density and reproductive success than those with songs in lower frequencies. This is because these high-frequency songs are not as strongly masked and are perceived more clearly by birds, thus increasing communication between bonded pairs. Some birds adapt to the presence of motorized sounds by increasing the amplitude of their song, singing earlier in the morning when motorized sounds are generally lower, or using mainly higher-pitched calls (Rheindt 2003). Shorebirds generally use less complex sounds to communicate than songbirds accompanied by a decreased range of song selection and frequency. Therefore, it may be more difficult for these birds to adjust their sound frequency by using mainly lower pitched calls, as their song repertoire may not include such calls. Therefore, shorebirds or other birds on Cape Hatteras with lower frequency, and/or lower amplitude calls may suffer more negative 'road' effects than those with higher frequency and/or louder calls. Effects may be limited by adjustments to song amplitude, timing and frequency by individual birds, depending on the flexibility, and innate song type of the species.

Predation risk for adult and nestling birds increases in areas with high-amplitude, low-frequency mechanical sounds (Lima 2009). Direct predator risk may increase because nesting birds are unable to detect auditory cues made by the predators (such as a redtail hawk scream or the cawing of a crow), and/or because they are unable to detect the warning calls of members of their own species or other birds in the area (e.g., the warning calls of a tern due to a circling hawk). These impacts are due to masking or distortion of the natural sounds in the environments by mechanical or human-associated sounds. Additionally, ORV and human sounds may themselves be considered a predation risk, and birds have been found to respond in areas of high-amplitude human-associated sounds in similar ways that they might respond in areas with high numbers of predators such as rodents or raptors (Lima 2009). Birds on Cape Hatteras may avoid such habitat, thus reducing the availability of prime nesting habitat containing the best cover and food sources. Birds may also respond by foregoing breeding altogether or reducing personal risk of predation by providing poorer quality care to fledglings (Lima 2009). These behavioral responses reduce the recruitment of young, limiting growth and sustainability of the population. Other behavioral changes include active flight, decreased foraging and increased vigilance, and a reduction in overall fitness levels. Exposure to frequent sound events, including ORV use and radios, would also

likely increase the intensity of their responses to all perceived predation threats (Rabin et al. 2006). These responses by shorebirds, including both direct and perceived or indirect predator risk, may decrease overall reproductive success for shorebirds using areas exposed to human associated and motorized sounds.

Researchers also found that, when all other factors (habitat quality) were equal, mechanical noise alone reduced the species diversity of nesting birds, resulting in changes to the natural bird communities in these areas. A controlled experiment provided strong evidence that noise alone, regardless of the presence of humans or moving motorized vehicles, negatively influences bird population levels and species diversity in much the same way as the physical destruction of or altering of a natural habitat (Francis et al. 2009). This effect is likely due to the masking of natural sounds by mechanical noise, which prevents many species of birds from successfully nesting in such areas. Increased mechanical sound levels altered species interactions, along with predator-prey interactions. This observation may explain why certain bird species (pigeons, sparrows, starlings), thrive in heavily human-influenced environments, and why species diversity in heavily mechanized sound-disturbed environments is low (Francis et al. 2009). Such effects may limit shorebird species diversity on Cape Hatteras, possibly increasing populations of human-tolerant species, while decreasing populations of species more sensitive to human-associated sounds. These effects may occur even in areas exposed to human-associated sounds, but removed from any visuals associated with such sounds, such as areas behind dunes, or where ORV travel is restricted. Effects depend on the audibility of motorized sounds in these areas, and will vary with the level of natural predation.

Nesting shorebirds at Cape Hatteras are exposed to a variety of natural and human caused sounds. Human caused sounds included motorized noise from ORVs and on-road vehicles, and human voices. Such effects may be species specific, as certain factors, including a higher song frequency (Rheindt 2003) and ability to nest near mechanized sound sources without increased stress or predation risk (Francis et al. 2009), may actually increase reproductive success of certain species. Birds have also shown ability to adapt certain behaviors, or ecological traits, when exposed to predation risk, decreasing the negative impacts of mechanized noise perceived as predator risk (Lima 2009).

### **EXISTING SOUND LEVELS**

The presence of millions of visitors to the Seashore engaging in various activities, coupled with the vehicular traffic through this Seashore along NC-12 and associated ramps, including ORV usage on the beaches, serve as sources of unnatural sounds within this Seashore. However, these sources are also considered to be consistent with the Seashore's purpose.

In order to determine the natural ambient sound levels within the Seashore and characterize the natural soundscape, the NPS Natural Sounds Program assisted the Seashore conduct acoustical monitoring within the Seashore. The sound level data collected by the Natural Sounds Program will facilitate the estimation of noise impacts from the use of ORV, serving as a comparative baseline condition to ORV noise.

A summary report of the sound level measurements, known as an "Acoustical Monitoring Snapshot," was developed by the NPS Natural Sounds Program and includes the locations of two representative sites where measurements were conducted, as well as a brief vegetative description for the sites and measured sound levels. The measured sound levels represent exceedance levels ( $L_x$ ) that describe the measurement data in terms of the decibel level that is exceeded  $x$  percent of the time during a given measurement period (i.e., an  $L_{10}$  value of 55 dBA indicates that the sound level is 55 dBA for 90% of the measurement and exceeds this level 10% of the measurement period). As the NPS is required to protect the natural soundscape, impact assessment is based on comparisons against the natural ambient sound levels. Natural ambient sound levels represent the natural environment, absent human-caused sounds, and may be well

estimated based on the  $L_{90}$  metric. The  $L_{90}$  metric represents the sound level exceeded 90 percent of the time.

Sound level measurements were conducted at two sites over a period of 31 days between May 2008 and June 2008. Sound level data were collected during a daytime (7:00 a.m. to 7:00 p.m.) and a nighttime (7:00 p.m. to 7:00 a.m.) period. Monitors were placed in secure locations, away from traffic and the beaches. Site one, labeled CH1 (figure 19), was located on Bodie Island Bone Yard just north of the fishing center and west of NC-12 on the side of the island near the sound. The site is composed of woody wetlands and mixed forest. Daytime existing  $L_{90}$  sound levels are 33.6 dBA while nighttime  $L_{90}$  sound levels are 33.8 dBA. Site CH2 (figure 20) is located at Cape Point on the ocean side within woody wetlands and shrublands. Existing  $L_{90}$  sound levels are 33.4 dBA during the daytime and 41.0 dBA during the nighttime period.

NPS protocols for acoustic monitoring at national parks (NPS 2006c) were followed in the collection of acoustic data at Cape Hatteras National Seashore to determine ambient conditions. The protocols attempt to capture spatial and temporal variability within the Seashore. Therefore, monitors are typically not placed near sound sources that would dominate and mask other acoustic resources (i.e., birds, insects). As noise from the surf is a predominant natural sound source along the beaches within this Seashore, the NPS Natural Sounds Program also provided published information on surf sounds to further characterize the natural soundscape within the Seashore.

Sounds from the surf vary, depending on how active the surf is (i.e., during high tide or stormy conditions the surf has more acoustic energy), and therefore sound levels may range between 20 dBA during less active periods and 55 dBA during more active periods (California State Lands Commission 2005). Additionally, surf noise is predominant on the beaches, but diminishes with increasing distance from the beaches, where vehicular noise sources may prevail from NC-12 and associated ramps and smaller feeder roadways. Acoustic conditions at the surf were extrapolated using the collected data. The results of the extrapolation were verified and corroborated by published sources (*Disposition of Offshore Cooling Water Conduits SONGS Unit 1 EIR*) and the experiences of Seashore managers.

FIGURE 19. ACOUSTICAL MONITORING SITE LOCATION FOR CH1

FIGURE 20. ACOUSTICAL MONITORING SITE LOCATION FOR CH2

## VISITOR USE AND EXPERIENCE

Visitation to the Seashore has shown a relatively steady increase, with occasional dips, particularly in the mid-1980s and recently from 2003 to the present. More than 2 million visitors have recreated at the Seashore every year since 1990 (see figure 21). Figure 22 illustrates visitor use data for 2005 through July 2010, which indicate that highest use occurs during June, July, and August; this accounts for approximately 47% of the annual recreation visits (based on 2009 data). Another 20% of annual visitation occurs during the fall (September, October, and November), 24% in the spring (March, April, and May), and 9% in the winter (December through February) (NPS 2008e). Overall, visitation at the Seashore in 2009 has been higher than 2008, with July 2009 visitation of 407,754 being the highest since 2003 (Murray pers. comm. 2009b).

**FIGURE 22. MONTHLY RECREATIONAL VISITATION AT CAPE HATTERAS NATIONAL SEASHORE, JANUARY 2005–JULY 2010**

## VISITOR CHARACTERISTICS

A study conducted by the University of Idaho during 1 week in July 2002 showed that many visitors (44%) were from North Carolina and Virginia, approximately 10% were from Ohio, and smaller proportions of visitors came from 29 other states and Washington DC. Over 50% of visitors were between 30 and 50 years of age (University of Idaho 2003).

## RECREATIONAL OPPORTUNITIES AND USE AT CAPE HATTERAS NATIONAL SEASHORE

The Seashore provides a diverse range of recreational opportunities including auto touring, biking, bird watching, boating, camping, fishing, hiking, hunting, kayaking, taking nature walks, horseback riding, stargazing, swimming, wildlife viewing, surfing, kite boarding, and wind surfing. Materials submitted to the negotiated rulemaking committee by Cape Hatteras Business Allies mentioned the following recreational activities sought by visitors: bird watching and wildlife viewing, fishing, horseback riding, shelling, sea glass collecting, swimming, water sports (kayaking, kite

**Historic Photo of Recreating at the Seashore**

boarding, paddle boarding, skim boarding, surfing, and windsurfing) (Cape Hatteras Business Allies 2009; NPS 2009m).

Major developed facilities, such as visitor centers and campgrounds, as well as more informal visitor use areas at the Seashore that provide for these recreational activities, are shown on the Seashore map in chapter 1 of this document. Visitor centers are located on each island in association with Ocracoke, Cape Hatteras, and Bodie Island lighthouses, and campgrounds include Ocracoke, Frisco, Cape Point, and Oregon Inlet. Fishing piers are located near Frisco<sup>8</sup> and at Avon and Rodanthe on Hatteras Island, and a major marina is located at Oregon Inlet on Bodie Island. Bathhouses and/or designated swimming beaches are available near Frisco on Hatteras Island, Coquina Beach on Bodie Island, and on Ocracoke Island north of the village. Information stations, day use areas, and informal recreation opportunities, such as nature trails, are also found throughout the Seashore. Visitor surveys were conducted in 2002 and 2010 regarding what facilities and activities visitors use while they are at the Seashore.

According to the study conducted by the University of Idaho in 2002, the three most important reasons mentioned by visitors for visiting the Seashore were the lighthouses, the beach/beachcombing, and fishing. Historical significance and swimming followed closely (University of Idaho 2003). This study also asked visitor groups to list the activities in which they participated during their visit to the Seashore. In total, 254 visitor groups were surveyed. Respondents could choose more than one activity in which they engaged, therefore the percentages did not equal 100%. The results are displayed in figure 23, with swimming/sunbathing being the most popular activity (approximately 200 or 78% of respondents), followed by visiting historic sites (approximately 180 or 70% of respondents), walking (approximately 165 or 65% of respondents), and enjoying solitude (approximately 143 or 56% of respondents). The study indicated 93 respondents (approximately 36%) had driven on the beach during their visit to the Seashore (University of Idaho 2003). Other activities that respondents participated in included family time/reunions, clamming/crabbing, shelling, shopping, and history study.

In addition to the 2003 study from the University of Idaho, the NPS contracted with RTI International to conduct an intercept survey of visitors using the oceanside beaches (RTI 2010a). The primary goal of the visitor intercept survey was to understand the current visitor use of the Seashore and how visitors' self-reported behavior would change under different management conditions.

The visitor intercept survey consisted of two separate sampling populations. The first sampling population was all visitors on open beaches in the Seashore from 6 a.m. to 10 p.m., between August 4, 2009 and March 29, 2010. The Seashore beaches were divided into 168 segments of varying lengths based on the expected number of visitors at the beach segment. To ensure that there was at least one three-day interview trip during the low winter season, two seasonal categories were created out of the 34 weeks in the first sampling population. Five trips were taken during the first category consisting of the 17 weeks between August 4 and November 30, 2009. One trip was taken during the lowest visitation category, which consisted of the 17 weeks from the beginning of December 2009 through the end of March 2010.

---

<sup>8</sup> The Frisco pier was closed for public safety reasons, due to deteriorating conditions, and then further damaged by Hurricane Earl in September 2010. The future of this pier is not known at this time.

Source: University of Idaho 2003

**FIGURE 23. VISITOR ACTIVITIES SURVEY RESULTS**

The second sampling population consisted of visitors at 12 selected beach areas in the Seashore from 10 a.m. to 6 p.m., Friday through Monday between June 15 and July 26 2010. The 12 selected beach areas were Oregon Inlet Campground Beach; Bodie Island Spit; Rodanthe Pier Beach; Avon Pier Beach; Cape Hatteras Lighthouse Beach; Cape Point; South Beach; Frisco Pier Beach; ramp 55 to Hatteras Inlet; North Ocracoke; Ocracoke Day Use Beach; and South Point Ocracoke.

Field staff conducting the survey took eight 3-day trips to the Seashore to interview beach visitors (six for the first sampling population and two for the second). Each selected day, field staff traveled to two randomly selected clusters of beaches and conducted interviews in two randomly selected beach segments per cluster. Two hours were allotted for interviewing in each beach segment. Groups of beach visitors were selected using systematic sampling based on the number of groups within the segment. In total, 96 beach segments were visited for interviews and 245 interviews were completed. The data from the counting trips were weighted based on sampling design and the probability that a segment was selected for counting at a certain time or a certain day.

Based on these surveys the most popular activities at the Seashore were swimming, sunbathing, or enjoying the beach and bird watching/wildlife viewing (see table 35-1). The activities driving on the beach during the day and beach fishing were done by an estimated 40.7% and 37.5% of visitors in the sampling population, respectively.

**TABLE 35-1. ACTIVITIES DONE SO FAR THIS TRIP - MEAN ESTIMATE AND 95% CONFIDENCE INTERVAL**

Activity	Mean	95% Confidence Interval	
		Lower Bound	Upper Bound
Pier fishing	5.5%	0.4%	10.6%
Beach fishing	37.5%	25.6%	49.4%
Charter (offshore) fishing	1.8%	0.0%	4.4%
Swimming, sunbathing, or enjoying the beach	99.4%	98.0%	100.0%
Surfing or kite-surfing	17.2%	4.2%	30.3%
Bird watching/wildlife viewing	70.7%	63.2%	78.2%
Taking a ferry	38.5%	10.7%	66.2%
Visiting the Cape Hatteras Lighthouse or Bodie Island Lighthouse	22.6%	9.0%	36.2%
Visiting historic sites in Cape Hatteras National Seashore	18.4%	9.3%	27.4%
Canoeing, kayaking, or sailing	6.2%	1.8%	10.7%
Driving on the beach during the day	40.7%	27.2%	54.2%
Driving on the beach at night after 10 p.m.	4.5%	0.7%	8.3%
Other	12.4%	2.0%	22.8%

Source: RTI 2010a

In the 2010 visitor intercept survey, some activities visitors engaged in the most were similar to those in the 2002 survey, with both showing a high number of respondents that participated in swimming/sunbathing (78% in 2002 and 99% in 2010). The 99% of respondents who indicated they engaged in swimming, sunbathing, or enjoying the beach may have also included those who were walking and/or enjoying solitude (which was not a category in the 2010 survey). Both surveys also showed similar numbers of respondents engaging in beach driving, with 36% indicating that they engaged in this activity in 2002 and 40% in 2010. However, results of the surveys differed for some activities, such as visiting historic sites, which had a high response in the earlier survey (70%) but a much lower response in 2010 (40%, comprising 22% who visited the Cape Hatteras Lighthouse or Bodie Island Lighthouse and 18% who visited other historic sites in Cape Hatteras National Seashore). Some of the differences between the two surveys may be explained by the slightly different survey locations. The 2010 survey was conducted only at beach areas. The earlier survey was conducted at Coquina Beach, Cape Point, ramp 43, Cape Hatteras Lighthouse and Visitor Center, Ocracoke Lighthouse and Visitor Center, Cape Hatteras ramp 4 (Oregon Inlet), Whalebone Information Center, Haulover Day Use Area, and Cape Point/Frisco Campgrounds.

For the 2010 survey, table 35-2 lists the weighted percent of the sampling population that selected each activity as their primary activity for the trip. Swimming, sunbathing, or enjoying the beach was the primary activity for 63.2% of visitors in the sampling population and surfing or kite-surfing was the primary activity for 6.9% of the sampling population. Beach fishing was the primary purpose of the trip for 22.8% of visitors, and driving on the beach was the primary purpose of the trip for 0.7% of visitors (RTI 2010a).

**TABLE 35- 2. PRIMARY ACTIVITY FOR THE TRIP - MEAN ESTIMATE AND 95% CONFIDENCE INTERVAL**

Activity	Mean	95% Confidence Interval	
		Lower Bound	Upper Bound
Beach fishing	22.8%	7.3%	38.2%
Swimming, sunbathing, or enjoying the beach	63.2%	48.8%	77.6%
Surfing or kite-surfing	6.9%	0.0%	16.5%
Visit the Cape Hatteras Lighthouse or Bodie Island Lighthouse	0.5%	0.0%	1.3%
Driving on the beach during the day	0.7%	0.0%	1.9%
Other	6.0%	0.0%	13.0%

Source: RTI 2010a

The 2010 survey also included questions regarding the current management of the Seashore. Table 35-3, shows that the awareness of beach driving among visitors to the Seashore was high, with 91.6% aware that some Seashore beaches are open to vehicles. Additionally, 58.7% of visitors were aware that some beaches previously open to vehicles are now closed at some point during the year. The uncertainty surrounding beach closures did not affect the planning of trips for 93.4% of visitors, however 4.2% of visitors reported making plans closer to time of the trip due to this uncertainty.

**TABLE 35-3. KNOWLEDGE AND IMPACT OF CURRENT MANAGEMENT - MEAN ESTIMATE AND 95% CONFIDENCE INTERVAL**

Question	Answer	Mean	95% Confidence Interval	
			Lower Bound	Upper Bound
Before you arrived at Cape Hatteras National Seashore for this trip, did you know that some beaches at Cape Hatteras National Seashore were open to vehicles?	Yes	91.6%	84.0%	99.3%
	No	8.1%	0.5%	15.8%
	Don't Know	0.2%	0.0%	0.6%
Before you arrived at Cape Hatteras National Seashore for this trip, did you know that certain parts of the Seashore that have been open to vehicles in the past are now closed to vehicles during parts of the spring, summer and fall?	Yes	58.7%	47.3%	70.0%
	No	40.1%	28.4%	51.9%
	Don't Know	1.2%	0.0%	2.7%
How would you say the uncertainty about whether specific parts of the Seashore would be open to vehicles affected when you started planning for this trip?	Didn't Affect	93.4%	88.1%	98.7%
	Farther in Advance	1.8%	0.0%	3.9%
	Made Plans Closer to the Time of the Trip	4.2%	0.2%	8.2%
	Don't Know	0.6%	0.0%	1.5%

## Recreational Fishing

**Historic Photo of Recreational Fishing**

Credit: NPS

The cold Labrador Current and the warm waters of the Gulf Stream meet adjacent to the Outer Banks of North Carolina. The waters off the Seashore are known throughout the world as highly productive fishing areas. The fish that congregate in the waters off the Outer Banks attract anglers from throughout the region, but largely from North Carolina and Virginia. In the spring and fall, when bluefish (*Pomatomus saltatrix*), spotted sea trout (*Cynoscion nebulosus*), red drum (*Sciaenops ocellatus*), and other species are present in offshore waters, surf fishermen line the beaches to cast their baits and lures over the incoming breakers and into the schooling fish. Most of the beach and sound are open to fishing as are the fishing piers in the villages of Rodanthe, Frisco, and Avon. NPS boat

ramps are located at the Oregon Inlet Marina and near the ferry office in Ocracoke Village. Charters and head-boat services (boats that carry a large number of anglers who pay by the person) are available at local marinas.

Particularly productive and high-demand fishing areas include Ocracoke, Hatteras, and Oregon inlets and Cape Point, which are often accessed via ORVs. ORV counts at ramps accessing these inlets exceeded those of other beach access ramps. This use is discussed in the “Visitor Access and Off-road Vehicle Use” section that follows below.

Typically, fishing tournaments occur in the spring and fall in locations throughout the Seashore, as shown in table 36. Tournament data from 2001 to 2008 indicate that, normally, about eight or nine fishing tournaments occur annually (Thompson pers. comm. 2008). While data are not available for actual attendance, the events are well attended. For 2005, estimates indicate that more than 720 people participated in one event that lasted

**Recreational Fishing in Modern Times**

Credit: NPS

for 2 days. Some tournaments may only have 25 participants, depending on the availability of fish and weather. Restrictions are placed upon the events as to location and times to ensure the availability of recreational areas for other Seashore visitors. These restrictions change from time to time depending on the time of the year, seasonal visitation figures, past experience with the sponsors, and how the proposed event is structured. Typically, Seashore beaches 0.5 mile on either side of Cape Point and 0.5 mile on either side of an inlet are closed to tournament fishing.

Like other Seashore visitors, tournament participants are not allowed in any resource closure areas. Tournaments take place in the designated ORV corridor, which has presented conflict with recreational anglers during the tournaments on a few occasions (NPS 2007e).

TABLE 36. FISHING TOURNAMENTS, 2004–2008

Applicant/Event	Tournament Date	# People Authorized	Tournament Location within the Seashore
4 Plus Four Wheel Drive Club	Late April from 2004 to 2008	600	Ocean beaches excluding 0.5 mile either side of Cape Point, 0.5 mile from Hatteras Inlet and Ocracoke Inlet, and 0.5 mile on the north side of Oregon Inlet
Ocracoke Invitational Surf Fishing Tournament	Late April / early May from 2004 to 2008	240	Ocean beach between ramps 68 and 72
Outer Banks Association of Realtors	5/20/2005	150	Ocean beach from Coquina Beach to ramp 4
Hatteras Village Invitational	Early September from 2006 to 2008	540	Hatteras Island
Hatteras Village Civic Association	9/10/2004 9/9/2005	240	Ocean beaches on Hatteras Island open to 4x4 vehicles from ramp 43 south and west to 0.5 mile from Hatteras Inlet, but excluding 0.5 mile either side of Cape Point
Salt Water Grill	9/28/2008	120	Bodie Island
Nags Head Surf Tournament	Early October from 2004 to 2008	240	Ocean beach from Coquina Beach to ramp 4
FFFF Tournament	Early October from 2006 to 2008	120	Bodie Island
Capitol City Four Wheelers	Mid-October from 2004 to 2008	600	Ocean beaches excluding 0.5 mile either side of Cape Point, 0.5 mile from Hatteras Inlet, and all areas closed to vehicular access including ramps temporarily closed due to flooding
Outer Banks Association of Realtors	Mid-October from 2006 to 2008	240	Bodie Island
Red Drum Tournament	10/24/2007 10/22/2008	600	Parkwide
Cape Hatteras Anglers Club	11/4/2004	600	Public ocean beaches excluding 0.5 mile either side of Cape Point, 0.5 mile from Hatteras Inlet and Ocracoke Inlet, and 0.5 mile on the north side of Oregon Inlet;
Cape Hatteras Anglers Club	11/3/2005 11/2/2006 11/8/2007 11/6/2008	720	Public ocean beaches excluding 0.5 mile either side of Cape Point, 0.5 mile from Hatteras Inlet and Ocracoke Inlet, and 0.5 mile on the north side of Oregon Inlet; also excluding 0.2 mile on either side of ramps 1, 4, 23, 27, 30, 34, 43, 49, and 55
Outer Banks Angler	11/30/2007 12/5/2008	600	Parkwide
Surf Fishing Info.	12/2/2005	240	Ocean beaches excluding 0.5 mile either side of Cape Point, 0.5 mile from Hatteras Inlet and Ocracoke Inlet, 0.5 mile on the north side of Oregon Inlet, and other closures ordered by the Seashore

### Visitor Access and Off-road Vehicle Use

As noted in chapter 1 of this document, before 1954, local residents and visitors used the beaches and sound trails for vehicular transportation purposes because there were few formal roads in this remote area. With the paving of NC-12, the completion of the Bonner Bridge connecting Bodie and Hatteras islands, and the introduction of the NCDOT Ferry System to Ocracoke Island, improved visitor access to the islands resulted in increased recreational use of the Seashore in general, as well as increased vehicle use on the beaches for recreational purposes. ORVs were used by residents to facilitate commercial netting of fish, and sport fishermen used ORVs to pursue migrating schools of game fish and to reach more productive areas such as Cape Point or the inlets, which are often a mile or more from the nearest paved surface. ORVs are currently used at the Seashore for commercial and recreational fishing, sightseeing, travel to and from swimming and watersport areas, and pleasure driving (NPS 2004b). On the other hand, Seashore visitors choose to access the Seashore by foot for swimming, sunbathing, birdwatching, fishing, enjoying scenic ocean views, and other recreational activities.

**Beach Driving at the Seashore**

Credit: NPS

**ORVs Accessing the Beach using a Ramp**

Credit: NPS

ORVs access the beach via a system of ramps located off NC-12. This vehicular beach access ramp system provides controlled entry and exit to beach areas. Originally, planks were placed on the dune crossing site, hence the name “ramp,” to prevent the sand from moving and to prevent the dune from being further breached. The ramps began as an informal system of unimproved access points connecting the roadway to the beaches. Over time, this system was formalized and ramps are now numbered, maintained, and identified on the Seashore’s ORV route maps as official vehicle routes for beach access. In 1978, there were 28

identified ramps, 22 of which were located on NPS lands. Although the NPS opened a new ramp to the public in 1998, the number of ramps has decreased since 1978 as some were lost to erosion and others were closed to the public and are now used for administrative vehicle access only (NPS 2004a). The NPS currently has 17 oceanside access ramps available for public ORV use. These ramps are listed on table 37. Each ramp number on the map (figure 24) refers to the approximate mile on NC-12 south of Nags Head on Bodie Island.

FIGURE 24. OFF-ROAD VEHICLE RAMPS AT CAPE HATTERAS NATIONAL SEASHORE

**Number and Distribution of ORVs at the Seashore**

From 2007–2008, the Seashore installed infrared counters at ORV ramps to determine the number of ORVs using the Seashore, as well as their distribution in the Seashore. However, in addition to counting ORVs, the counters were found to count anything that breaks the infrared beam, including pedestrians, rain, and untrimmed plants. The counters also failed to register some counts and must be properly aligned to count. Testing showed that the ramp counters overestimated the number of ORVs substantially and that pedestrian crossings often added to the inaccurate counts. For these reasons, the data from the ramp

counters were deemed not reliable for constructing estimates of ORV use at the seashore (RTI pers. comm. 2009a).

On Memorial Day and the Fourth of July, the Seashore counts the number of ORVs on the beach by an aerial survey. RTI (RTI pers. comm. 2009a) used this information, along with assumptions based on rental occupancy and patterns of use, to create a range of estimates for the total number of ORVs using the Seashore in a year. Although there are some data from various sources about the number of vehicles on the beach, none of the sources have the scope or reliability to provide a robust annual estimate of vehicles on the beach. The data from the aerial counts were used to provide counts for ORVs at the following locations, which include some of the most popular ramps leading to the points and spits:

- Ramp 4: Includes Bodie Island Spit.
- Ramp 23 to ramp 27: Approximately 4-mile area directly south of Salvo.
- Ramp 27 to ramp 38: Approximately 11 mile area including Avon.
- Ramp 43 to ramp 49: Includes Cape Point.
- Ramp 55: Includes Hatteras Inlet Spit.
- Ocracoke: All of Ocracoke Island.

Figure 25 and the ramp counts in table 37-1 show the distribution of ORVs across these areas on Memorial Day and the Fourth of July in 2008.

**FIGURE 25. ORV DISTRIBUTION BASED ON AERIAL COUNTS, FOURTH OF JULY AND MEMORIAL DAY 2008**

<b>2008 Total Count</b>	<b>2069</b>	<b>2008 Total Count</b>	<b>2579</b>

Trevino pers. comm. 2010

To supplement these counts, a survey was conducted according to a random sampling plan to provide an estimate of the number of vehicles on the beach between April 1, 2009, and March 30, 2010, with a 95% confidence interval. NPS contracted with RTI to conduct a count of vehicles using the oceanside ORV beach access ramps over a 12-month period from April 2009 through March 2010. The primary goal of the vehicle counting survey was to estimate the total number of vehicle roundtrips on the 17 oceanside ORV ramps during a 12-month period between 6 a.m. and 10 p.m. The details of the study are described in the final report (RTI 2010b). These vehicle counts provide an estimate of the total number of vehicle roundtrips to the beach. They are not directly comparable to the official number of recreational visitors to Cape Hatteras, because these numbers are determined by a traffic counter at Whalebone Junction. A single recreational visit, as counted by the Whalebone Junction counter, can include multiple vehicle roundtrips over an ORV ramp to the beach. Seventeen oceanside ORV access ramps currently operate in the Seashore. Two of the ramps are located on Bodie Island, ten are on Hatteras Island, and the remaining five are on Ocracoke Island. RTI field staff took 19 three-day trips to the Seashore to count at beaches and ramps, for a total of 57 days of counting. Each selected day, field staff traveled to two randomly selected clusters of ramps and beaches and spent two hours counting the number of vehicle roundtrips on each of two ORV ramps (the numbers of entrances and exits were added together and averaged to provide the estimated number of roundtrips since each vehicles that entered the beach through a vehicle access ramp also exited the beach, though not necessarily at the same ramp). The 57 days of counting resulted in a total sample of 114 clusters covering 228 two-hour vehicle counting opportunities and 456 beach counting opportunities (RTI 2010b).

To ensure that at least two counting trips were taken during the low winter season, RTI created two seasonal categories out of the 52 weeks. The two categories roughly correspond to low and medium/high visitation seasons at the Seashore. The lowest visitation category, which consisted of the 17 weeks from the beginning of December 2009 through the end of March 2010, was assigned two 3-day trips. The remaining 17 trips took place during the other 35 weeks from April 2009 through November 2009, which make up the medium and high visitation categories. The data from the counting trips was weighted based on the sampling design and the probability that a ramp was selected for counting at a certain time or a certain day. Based on the data from the ramp counts, the mean estimate is 499,802 vehicle roundtrips over an oceanside ramp onto the Seashore beaches between April 2009 and March 2010, with a 95% confidence interval of 276,946 to 722,659. An estimated mean of 994,604 passengers were inside these vehicles with a 95% confidence interval of 654,961 to 1,334,247 passengers (table 37-2). As with the number of vehicle roundtrips, the estimated number of passengers is not directly comparable to the official statistics on recreational visitors to the Seashore. A visitor using the ramps could make several

roundtrips over the ramps in a day and would result in counting the same visitor multiple times (RTI 2010b).

The increased sampling coverage between April and November (49% of the weeks as opposed to 12% of the weeks between December and March), resulted in narrower confidence intervals around the April and November estimates. Between April and November, the 95% confidence interval is +/-17% of the point estimate of 344,999 vehicle roundtrips. Between December and March, the 95% confidence interval is +/-151% (table 37-2). In addition, the geographic distribution of ORV use in the Seashore could not be determined between December and March due to the lack of sampling coverage. April through November captures the majority of vehicle roundtrips that would be affected by the proposed management alternatives, providing the best estimates (RTI 2010b).

**TABLE 37-2. ESTIMATES AND 95% CONFIDENCE INTERVALS FOR NUMBER OF VEHICLES MAKING A ROUNDTRIP TO THE BEACH OVER AN OCEANSIDE RAMP AND ASSOCIATED PASSENGERS BY TIME CATEGORY**

Time Interval	Vehicle Roundtrips			Passengers		
	Estimate	95% Confidence Interval		Estimate	95% Confidence Interval	
		Lower Bound	Upper Bound		Lower Bound	Upper Bound
April 2009 to November 2009	344,999	284,696	405,302	768,948	625,928	911,968
December 2009 to March 2010	154,803	0	392,594	225,656	0	567,185
52 week total	499,802	276,946	722,659	994,604	654,961	1,334,247

NOTE: These vehicle access counts provide an estimate of the total number of vehicle roundtrips to the beach. Currently the NPS method for compiling visitation only uses the Whalebone Junction counts because a vehicle using the ramps could make several roundtrips in a day and would result in counting the same visitor multiple times.

Source: RTI 2010b

Table 37-3 reports the average daily vehicle roundtrips and associated passengers by ramp for the period of April to November 2009. The most popular ORV ramp between April and November was ramp 4 on Bodie Island, however ramps 43, 49, 55, and 70 were all estimated to average over 100 vehicle roundtrips a day between April and November 2009. These results were similar to the 2008 counts, which found that ramp 4 and ramps 43-49 were the most travelled ramps on both Memorial Day and Fourth of July (see figure 25 and table 37-1). During the 2009 vehicle counts, an estimated 59% of vehicle roundtrips took place on the various ramps on Hatteras Island, 26% on Ocracoke Island, and 15% on Bodie Island (table 37-3). Confidence intervals for the vehicle roundtrip estimates range from +/-18% for ramp 70 to +/-132% for ramp 44. These results for Hatteras Island are similar to the 2008 counts in figure 25 and table 37-1, which showed approximately 55% of vehicles on Hatteras Island on Memorial Day and 63% of vehicles on Hatteras Island on July 4. The 2008 vehicle counts for Bodie and Ocracoke islands on Memorial Day and July 4 differed slightly from the 2009 counts. The 2008 vehicle counts for Bodie Island (ramp 4 to Bodie Island Spit) showed approximately 31% on Memorial Day and 25% on July 4; the 2009 counts showed 15%. The 2008 vehicle counts for Ocracoke Island showed approximately 14% on Memorial Day and 12% on July 4; the 2009 counts showed 26%.

**TABLE 37-3. ESTIMATES AND 95% CONFIDENCE INTERVALS FOR DAILY VEHICLE ROUNDTRIPS AND ASSOCIATED PASSENGERS BY ORV RAMP (APRIL TO NOVEMBER 2009)<sup>a</sup>**

Ramp	Vehicle Roundtrips			Associated Passengers		
	Estimate	95% Confidence Interval		Estimate	95% Confidence Interval	
		Lower Bound	Upper Bound		Lower Bound	Upper Bound
2	40.4	26.8	54.1	66.2	40.8	91.6

72	76.4	14.5	138.3	167.4	28.6	306.3

<sup>a</sup> These vehicle access counts provide an estimate of the average daily number of vehicle roundtrips to the beach. Currently the NPS method for compiling visitation only uses the Whalebone Junction counts because a vehicle using the ramps could make several roundtrips in a day and would result in counting the same visitor multiple times.

Source: RTI 2010b

**Closures.** A number of areas throughout the Seashore have been closed to ORV travel over the years, either due to safety issues or for resource protection purposes. Temporary closures to ORVs also occur along the beaches to protect sea turtle nests and bird species such as piping plovers, American oystercatchers, and colonial waterbirds. The Seashore contains approximately 67 miles of shoreline that are available for public use, when not closed for resource or safety concerns. The 12 miles of beach that comprise Pea Island NWR are within the Seashore boundary and are managed separately and under a different regulatory framework by the USFWS; ORVs are not permitted on Pea Island beaches.

Currently, all the Seashore beaches are potentially open to ORV use during the winter, except a section near the Cape Hatteras Lighthouse (which is closed year-round), and those beaches under a safety closure. Some beaches are also closed to ORV use if they become too narrow. During the summer months, the amount of Seashore beach open can vary depending on resource closures and seasonal ORV closures of village beaches, as detailed in chapter 2 of this document. On the soundside, 18 access points are publicly available to ORVs. However, vehicular access is typically limited to short distances along sandy portions of the sound shoreline because the Seashore prohibits ORV use on vegetated areas, and most of the soundside areas have vegetation. Closures vary from year to year depending on a range of management considerations.

Following Hurricane Isabel, ORV use areas (restrictions) were put in place in March 2004 to protect sensitive habitat that opened up as a result of dune destruction and to provide for more consistent management of breeding and nesting bird closures. These closures did not significantly decrease the sum total of shoreline miles open to ORV access and public recreation nor did it impact the number of ramps open to allow ORV access to Seashore beaches. White posts were placed 150 feet landward from the average, normal high-tide line, or, if existing, at the vegetation or remnant dune line. Beach areas landward of the post line, although not open to ORV use, were open to pedestrian use (NPS 2004b).

Temporary resource closures are established throughout the Seashore, including within areas of ORV and pedestrian use, to comply with protection measures afforded nesting sea turtles and protected shorebirds. These closures are implemented at crucial periods during the life of these species. During these closures, the NPS routes ORV beach traffic around the temporary resource closure when possible. Temporary resource closures apply to both ORV and pedestrian use, although occasionally pedestrian access can be provided in pedestrian corridors. These closures include prenesting closures. Table 37-4 details the prenesting closures or resource closures that have taken place under alternative A (2007) and alternative B (2008 – 2010), beginning in 2007, showing dates when the closure began and when the area reopened.

**TABLE 37-4. RESOURCE CLOSURE DATES FOR POPULAR VISITOR SITES 2007-2010**

<b>2007 (Prenesting areas installed by April 1)</b>			
<b>Location</b>	<b>Closed</b>	<b>Reopened</b>	<b># of Days Closed</b>

2010 (Prenesting areas installed by March 15)			
Location	Closed	Reopened	# of Days Closed
Bodie Island Spit	May 9	August 23	106
Cape Point	May 13	July 7/July 21 (Pedestrian/ORV)	55/69
Hatteras Inlet "rip"	March 11	July 15	126
North Ocracoke	April 28	August 25	119
South Point Ocracoke	April 20	August 27	129

<sup>1</sup> Open to ORVs/pedestrians from east side, but not from west side

<sup>2</sup> Open to pedestrians only from soundside (south of terminus of Spur Road). Pole Road safety closure after a storm prevented access to Spur Road May 8-9. Ocean shoreline approximately 0.3 mile south of Pole Road closed to ORVs and pedestrians as prenesting area on March 28, then reopened on June 30 (94 days closed).

<sup>3</sup> Open to ORVs and pedestrian North of ramp 59 approximately to the inlet.

<sup>4</sup> Closed to access on June 26 (PIPL chicks); re-opened for daytime access on June 28; and re-opened to 24-hour access on July 2.

<sup>5</sup> Closed to access on evening of July 9 (AMOY chick); re-opened for daytime access on July 11; and re-opened for 24-hour access on July 16.

**Bird Closures.** The open sand flats near the three inlets in the Seashore (Oregon, Hatteras, and Ocracoke) and Cape Point are used by protected bird species and are also favorite fishing areas that visitors access in ORVs. Piping plover, American oystercatcher, and colonial waterbird breeding activity has been documented on and near the ocean beach in all of these locations.

In 2005, temporary resource closures occurred at multiple beach locations (including popular recreational fishing areas at the points and spits) to protect piping plovers, American oystercatchers, and colonial waterbirds from ORV and pedestrian use. These closures occurred on all three islands but were most concentrated on Hatteras Island, followed by Ocracoke. The Interim Strategy was published in January 2006 and finalized by a FONSI in July 2007 (NPS 2007a). The Interim Strategy presented a multifaceted approach that included the establishment of prenesting closures, species protection buffers, wintering habitat protection, and temporary resource closures. Although for the most part the Interim Strategy established specific distances for species buffers, it allowed for the reduction or expansion of buffers based on professional judgment of the resource management staff. Species and ORV management under the Interim Strategy resulted in beach closures similar to those that occurred in previous years. Management and resource closures were altered by a lawsuit in 2007 and subsequent consent decree in 2008.

In October 2007, Defenders of Wildlife and the National Audubon Society filed a lawsuit against the NPS alleging inadequacies in the management of protected species at the Seashore under the Interim Strategy and failure of the Seashore to comply with the requirements of the ORV executive order and NPS regulations regarding ORV use. On December 18, 2007, the Dare County Commissioners, Hyde County Commissioners, and the board of the Cape Hatteras Access Preservation Alliance were allowed to join the lawsuit as intervenor-defendants. However, a consent decree was filed on April 16, 2008, in U.S. District Court (signed on April 30, 2008), whereby the parties involved in the lawsuit agreed to a settlement of the case. The consent decree resulted in larger

**Typical Closure**

Credit: NPS

buffers than those prescribed in the Interim Strategy being established during portions of the spring and summer around bird breeding and nesting areas; this included creating a 1,000-meter (3,280-foot) vehicle buffer and a 300-meter (984-foot) pedestrian buffer around piping plover chicks until they have fledged. From May 15 through August 21, 2008, an average of 10 miles of oceanfront beach at the Seashore was closed to both pedestrians and ORVs. The largest amount of beach closures was reported on May 29, 2008, when 12.8 miles of beach were closed to all recreational use to protect piping plovers exhibiting breeding, nesting, and/or foraging behavior. The consent decree also established a prohibition on night driving on beaches between the hours of 10:00 p.m. and 6:00 a.m. from May 1 through September 15, with night driving allowed from September 16 through November 15 under the conditions of a permit.

**Sea Turtle Closures.** Temporary resource closures, which apply to ORVs and pedestrians, are implemented during nesting and hatching activities for all three sea turtle species that are known to nest at the Seashore. Generally, ORVs and pedestrians can negotiate around these posted closures for sea turtle nests. However, when the turtle eggs are ready to hatch, the NPS implements a beach closure with fencing from the nest to the water's edge. If sufficient room exists, ORVs and pedestrians can go around the landward side of the fence. In some cases, a full beach closure must be implemented because of the location of a nest relative to a dune or vegetation, preventing ORV and pedestrian access through the area. As mentioned previously, the consent decree signed in April 2008 included a prohibition on night driving to protect nesting sea turtles. The consent decree also contains provisions for full beach closures in the fall to allow existing turtle nests to hatch safely.

**Safety Closures.** Areas normally open to ORVs may close for safety reasons. Adverse weather conditions can result in narrow beach areas or flooded conditions, among other hazards, necessitating closures to vehicles. In November 2005, safety closures included 1.6 miles on Bodie Island, 22.8 miles on Hatteras Island, and 6.5 miles on Ocracoke Island (Stevens pers. comm. 2005). However, from May 15 through August 21, 2008, safety closures throughout the season consistently included a total of 11.1 miles of beach (NPS 2008m). Under current management, village beaches are closed to ORVs to protect pedestrians during the busy summer season.

## **CROWDING, VISITOR ENCOUNTERS, AND VISITOR SAFETY**

A University of Idaho study indicated that one of the reasons people visited the Seashore was to escape crowds and seek solitude. When asked about crowding, 27% of visitors said they felt "crowded" to "extremely crowded," while 43% of visitors felt "somewhat crowded." Thirty percent of visitors surveyed indicated that they felt "not at all crowded." Many visitor groups (49%) reported that crowding "detracted from" their park experience (University of Idaho 2003).

As part of the visitor experience, visitor safety is also considered. During public scoping for this plan/EIS, comments were received that indicated that some visitors felt that there was a potential for conflicts between visitors on foot and visitors using ORVs. The potential for accidents involving ORVs and pedestrians on beaches open to ORV use is well documented. For example, during 2010 in separate incidents in Volusia County, Florida, two children were run over and killed by ORV, one on New Smyrna Beach and one on Daytona Beach Shores (Cave 2010). Since 2005, 41 pedestrians have been hit by cars on the Volusia beaches (Hobson 2010). At the Seashore, law enforcement staff indicated in early 2009 that in the prior 10 years, there were no known case incident reports documenting pedestrians being struck by ORVs on Seashore beaches; however, public comment indicated a concern about the speed of ORVs on the beach and how close they are to other Seashore users. On September 27, 2009, a 7-year-old boy was accidentally hit by an ORV that was backing up on the beach in front of ramp 38. While the boy's parents and other family members were swimming and playing in the ocean, the boy decided to play on the beach digging holes and making sand castles with his hands. The driver of the vehicle that struck the boy had driven onto the beach to see if he and his passenger would surf at this location. The

individuals decided not to surf at this location and turned around to exit the beach. The beach is sloped from the ramp down to the water and the sand is soft in this area. The vehicle driver was having difficulty driving his vehicle up the slope and was backing up and going forward to try to get up the slope, (they had not reduced air pressure in their tires). While backing up, the driver did not see the boy playing in the sand. The vehicle struck the boy with the right rear bumper and tire. Neither of the boy's parents had observed the actual incident but had observed the vehicle maneuvering on the beach prior to the accident. They did not believe the vehicle was being operated carelessly or too fast. The boy was transported to the Outer Banks Hospital for examination and was released. Injuries included bruising to the arm and leg. The ORV operator was not charged with any violation (Murray pers. comm. 2009a).

## VISITOR SATISFACTION

A visitor survey was conducted by the University of Idaho Park Studies Unit for units of the NPS in 2008. The survey was developed to measure each park unit's performance related to NPS *Government Performance Results Act* (GPRA) Goals IIa1 (visitor satisfaction) and IIb1 (visitor understanding and appreciation). Survey cards were distributed at the Seashore to a random sample of visitors from July 1 to July 31, 2008. The report included three categories of data: park facilities (which included visitor centers, exhibits, restrooms, walkways/trails/roads, and campgrounds / picnic areas), visitor services (assistance from park employees, park maps/brochures, ranger programs, and commercial services), and recreational opportunities (nature/history/cultural learning and outdoor recreation). Overall, the percentage of Seashore visitors satisfied with the three categories of facilities, services, and recreational opportunities taken together, was 95%. When asked about each component separately, 93% of visitors were satisfied with park facilities, 85% of visitors were satisfied with visitor services, and 89% were satisfied with recreational opportunities (University of Idaho 2008).

In the 2002 University of Idaho study, the researchers solicited visitor opinions about selected factors that affect visitor experience. As would be expected, vehicles on the beach were perceived very differently by different visitors, but most stated that the use of vehicles on the beach did not detract from their visitor experience. The factors receiving the highest proportion of "no effect" ratings were airplane overflights (50% of those surveyed), dogs off leash (35%), vehicles on the beach (34%), and visitors drinking alcohol (33%). Factors receiving the highest proportion of "added to my experience" ratings included vehicles on the beach (20%) and fires on the beach (16%), while those receiving the highest "detracted from my experience" ratings were litter (40%) and vehicles on the beach (18%). About 29% of those surveyed did not experience vehicles on the beach (University of Idaho 2003).

## Night Skies

The NPS defines a natural lightscape as "a place or environment characterized by the natural rhythm of the sun and moon cycles, clean air, and of dark nights unperturbed by artificial light. Natural lightscapes, including dark night skies, are not only a resource unto themselves, but are an integral component of countless park experiences"

(NPS 2007b). The NPS created the Night Sky Team in 1999 to address increasing alarm over the loss of night sky quality throughout the network of national parks. The Night Sky Team functions as a center of

This picture was compiled from images captured on a boardwalk between Frisco and Hatteras. Frisco lies at about 60° azimuth and Hatteras at about 260° azimuth.

Credit: Night Sky Team Visit Report

expertise that provides advice, guidance, and technical support in characterizing and preserving park lightscares (NPS 2007b). According to the Night Sky Team, the Seashore is one of only a handful of sites in the eastern United States with a nearly natural regimen of light and dark, where light patterns are made up primarily of the dark sky, moon, and stars (NPS 2008f).

This picture was compiled from images captured on a boardwalk between Salvo and Avon. The combined light of Rodanthe, Salvo, and Waves can be seen at about 6° and Avon at 191°. Also note the presence of a few clouds reflecting the town lights at about 345°.

Credit: Night Sky Team Visit Report

In November 2007, the NPS Night Sky Team visited the Seashore to record preliminary measurements of night sky quality from three sites: the Bodie Island Maintenance Facility (Bodie Island); the boardwalk at ramp 27 (Hatteras Island); and the boardwalk south of Frisco (Hatteras Island) (NPS 2008f). During this visit, the team concluded that the Seashore has better night sky quality as compared to most other NPS

units east of the Mississippi River. Furthermore, measurements showed that light pollution sources beyond the Seashore boundary illustrated the need to be aware of the easily impacted night skies (NPS 2008f).

Measurements of the night sky at the Seashore were taken with a charge-coupled device (CCD) camera (a scientific-grade digital camera) that captures the known magnitude (a measure of stellar brightness) of known stars as an index to determine the ambient brightness of the nighttime sky. These measurements are influenced by atmospheric conditions, which affect how light travels through the sky. To account for these changes, multiple measurements are taken over a period of time. The initial measurements at the Seashore occurred over two nights, with more planned in the future (NPS 2008f).

Results from the November 2007 measurements found that sky brightness ranged from approaching a natural level of darkness to significantly light polluted, with the potential to threaten the ecological health of the coastal environment in some areas (NPS 2008f). To address those areas where there are high levels of light pollution, the Night Sky Team recommended retrofitting or swapping existing light fixtures in favor of turtle-friendly and night-sky-friendly fixtures, as well as working with park neighbors to enact night sky measures such as lighting ordinances (NPS 2008f).

This picture was compiled from images on Bodie Island, just south of the maintenance facility. A number of light domes are evident in this image, including the combined light from Harbor, Rodanthe, and Salvo between 165° and 168°; the lighthouse at 184°; Wanchese at 267°; and the combined light from Manteo, Kill Devil Hills, Nags Head, and Kitty Hawk between 304° and 333°. A considerable amount of light scattering occurs in this picture due to high humidity.

Credit: Night Sky Team Visit Report

## **SOCIOECONOMIC RESOURCES**

This section describes the social and economic environment that potentially would be affected by the proposed alternatives. The social and economic environment of a region is characterized by its demographic composition, the structure and size of its economy, and the types and levels of public services available to its citizens.

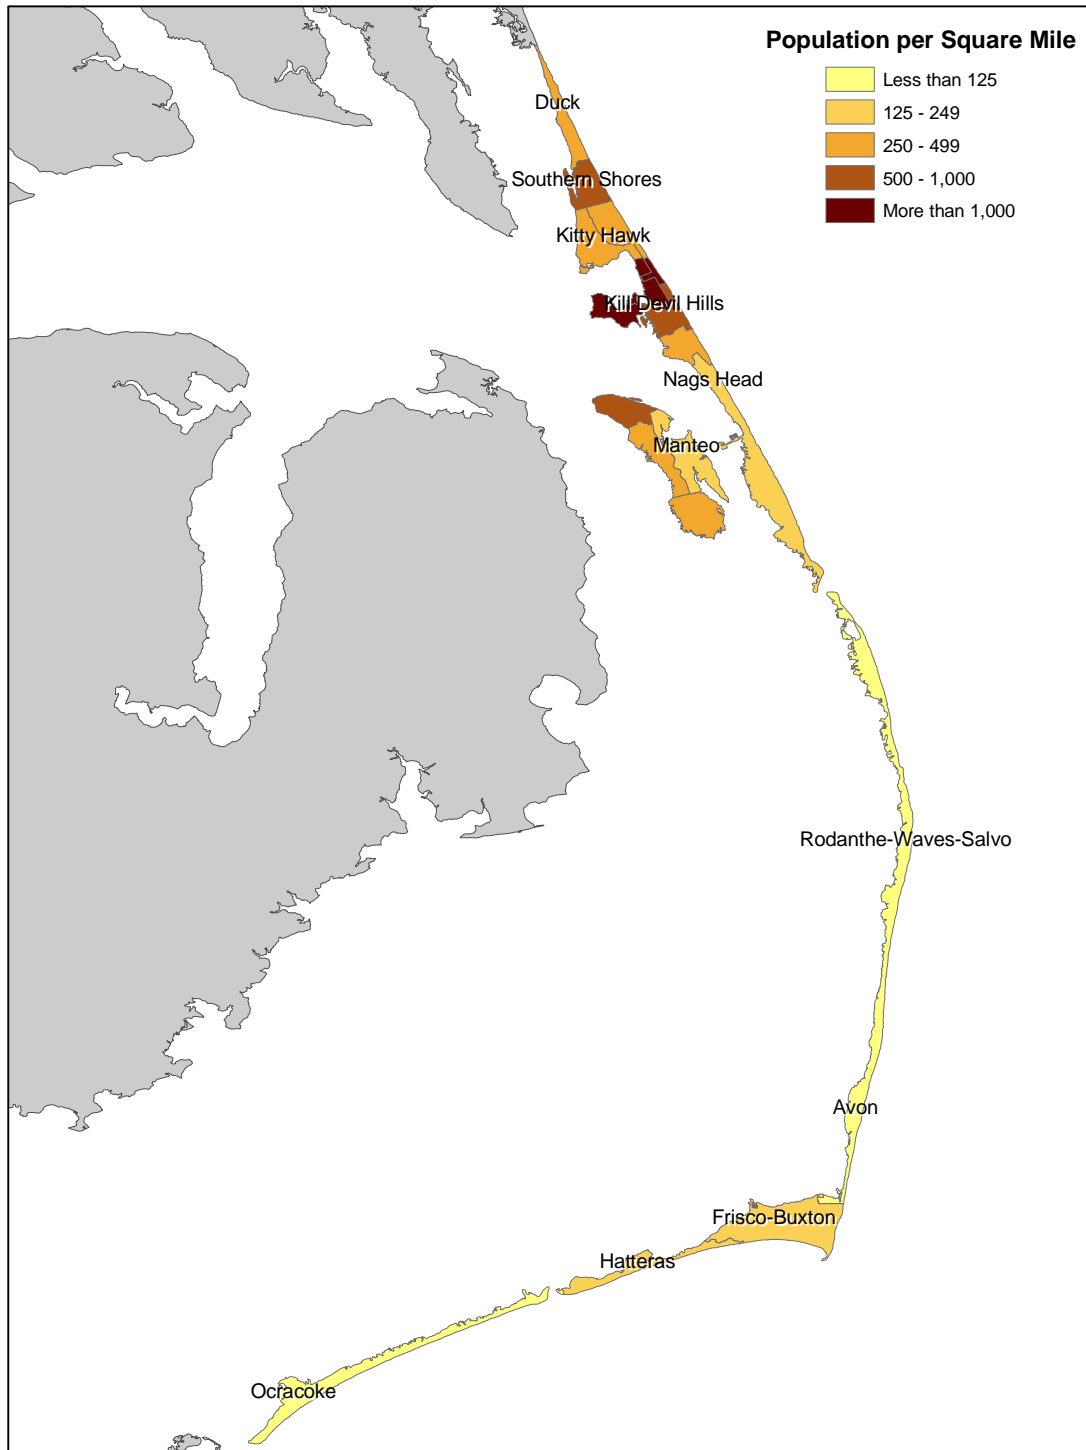

The socioeconomic environment evaluated for this plan/EIS encompasses the Outer Banks portion of two counties in North Carolina—Dare and Hyde. Hatteras and Bodie islands are part of Dare County while Ocracoke Island is within Hyde County. This area contains thirteen zip codes, eighteen of the nineteen block groups in Dare County, and one of the four block groups in Hyde County. Data not available at the block group or zip code level will be reported at the county level.

The Outer Banks portion of Dare and Hyde counties forms the economic region of influence (ROI) and defines the geographic area in which the predominant social and economic impacts from the proposed alternatives are likely to take place. The largest towns within the ROI include Nags Head, Kill Devil Hills, and Kitty Hawk, which are located on Bodie Island north of the Seashore. The villages of Ocracoke, Hatteras, Frisco, Buxton, Avon, Salvo, Waves, and Rodanthe would be most affected by the proposed actions because they are located within the Seashore and depend most directly on tourists visiting the Seashore for their livelihood. As discussed in the following sections, the northern part of the ROI, which is not adjacent to the Seashore, has a larger population and a larger business community. Although the relative impact of changes in visitation to the Seashore will be greater for the villages located within the Seashore, the economic base is larger in the part of the ROI north of the Seashore. The result is that smaller relative changes to businesses north of the park could generate similar total revenue changes to the changes experienced in the villages within the Seashore.

### **DEMOGRAPHICS**

The economic ROI is primarily rural in character, although portions of Dare County, especially in the north, are developed with large tracts of vacation homes and small businesses that support the area's robust tourism industry. Much of Dare County's permanent population also resides in this area, the most densely populated portion of the ROI (figure 26). Note that data presented are often taken from the U.S. Census Bureau. The census places people according to "usual residence" guidelines, so people are counted where they live most of the year.

Source: Environmental Systems Research Institute, Inc. 2002

**FIGURE 26. 2000 POPULATION DENSITY BY BLOCK GROUP**

In recent years, population trends have differed substantially for Dare and Hyde counties. Table 38 provides population statistics for the state of North Carolina, Dare and Hyde counties, and the Dare and Hyde County block groups located on the Outer Banks. Between 2000 and 2008, Dare County's population grew 12%, from 29,967 to 33,584. This is a slightly lower percentage change in population than the state of North Carolina as a whole. However, the portion of the state population occupying Dare County remained 0.4%. During this same time period, the population of Hyde County decreased by 11%, from 5,826 to 5,181 (U.S. Census Bureau 2008a), lowering the portion of the state population occupying Hyde County from 0.07% to 0.06%. The Dare County block groups within the ROI account for 96% of Dare County's population, while Hyde County block group represents only 13% of Hyde County's population (U.S. Census Bureau 2000).

**TABLE 38. POPULATION STATISTICS**

Geographic Area	2000 <sup>a</sup>	2007 <sup>b</sup>	2015 <sup>c</sup>	2029 <sup>c</sup>	Percent Change, 2000–2007	Percent Change, 2000–2029

<sup>a</sup> U.S. Census Bureau 2000

<sup>b</sup> Population Division, U.S. Census Bureau 2009a

<sup>c</sup> Office of State Budget and Management, North Carolina 2009

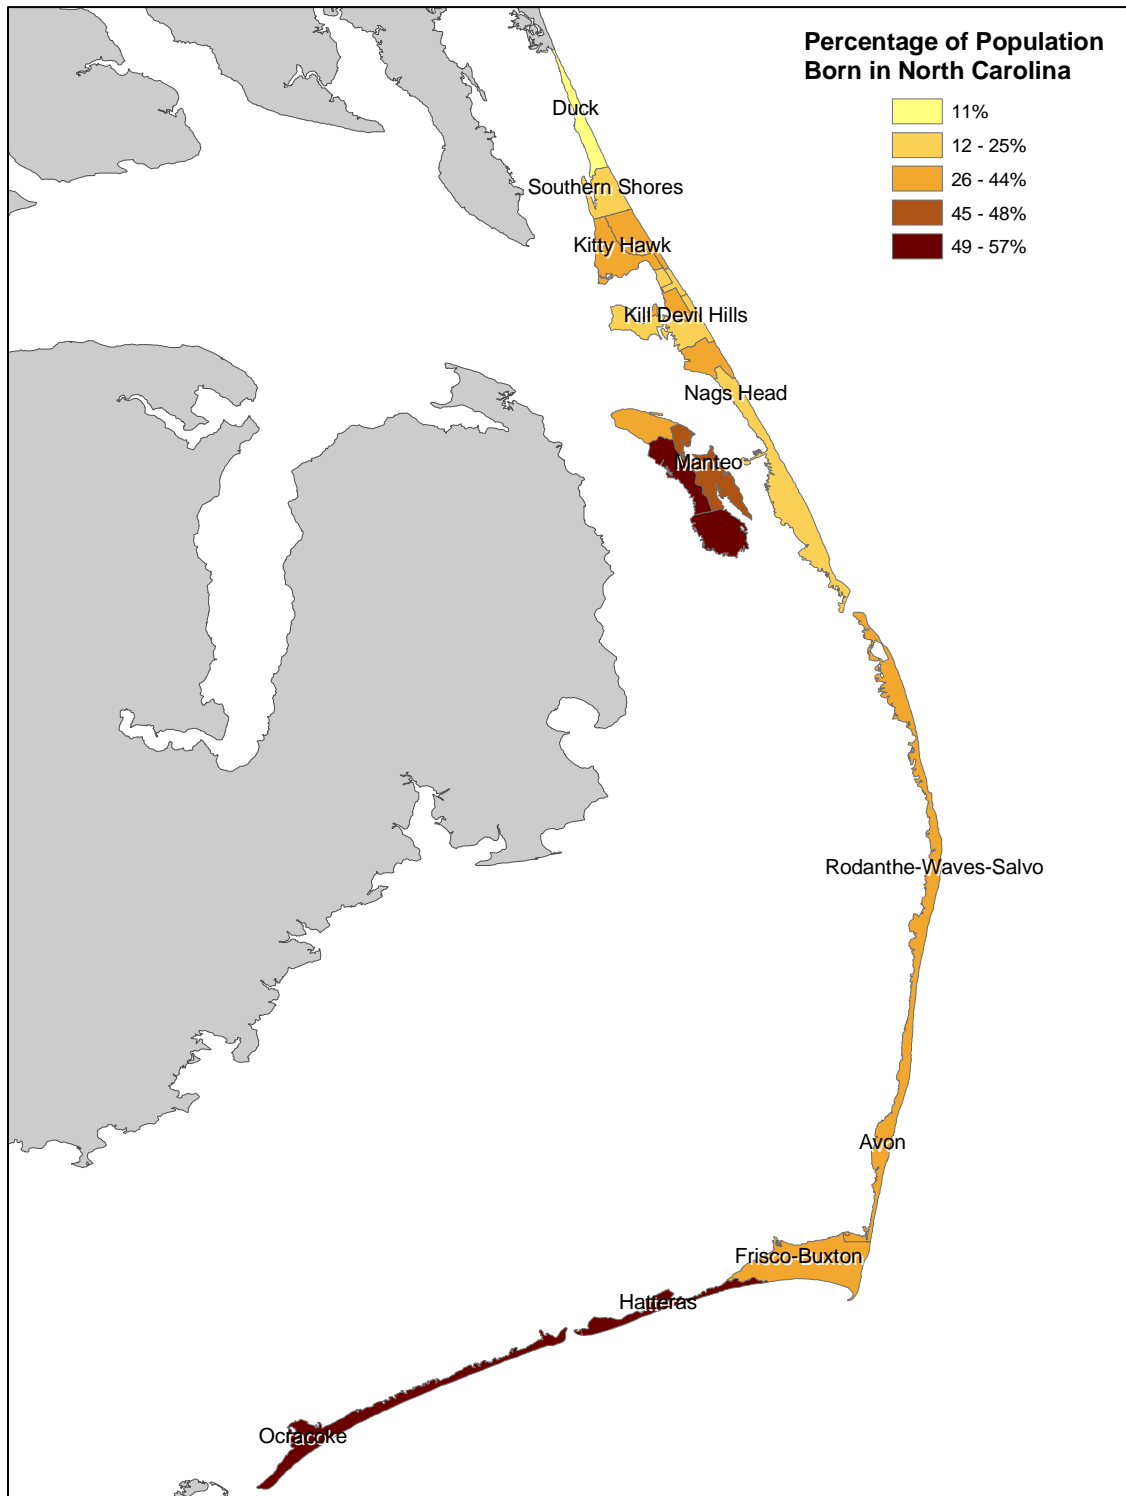

<sup>d</sup> The 18 Dare County block groups in the ROI

<sup>e</sup> The one Hyde County block group in the ROI

According to population projections published by the North Carolina Office of State Budget and Management's State Demographics unit, the state and Hyde County population trends are expected to continue into the foreseeable future, while Dare County is projected to lose residents. By 2029, the population in Dare County is projected to decrease to 26,053, a 13% reduction relative to 2000. The population of Hyde County is expected to fall further to 4,717, a 19% decrease relative to 2000 (Office of State Budget and Management North Carolina 2009).

Demographic and economic trends during the last three decades have contributed to growing differences in the population characteristics and income levels in the different areas of the ROI. The rate of change is especially rapid in northern Dare County, where a smaller percentage of residents were born in North Carolina, shown in figure 27.

In 1999, the areas within the ROI had a 13% greater per capita income than North Carolina as a whole, and 6% greater than the country as a whole (table 39). This distribution varies across the ROI. Ocracoke, southern Dare County, and portions of Roanoke Island all had a lower per capita income than the more densely populated block groups in the northern part of the ROI (figure 28).

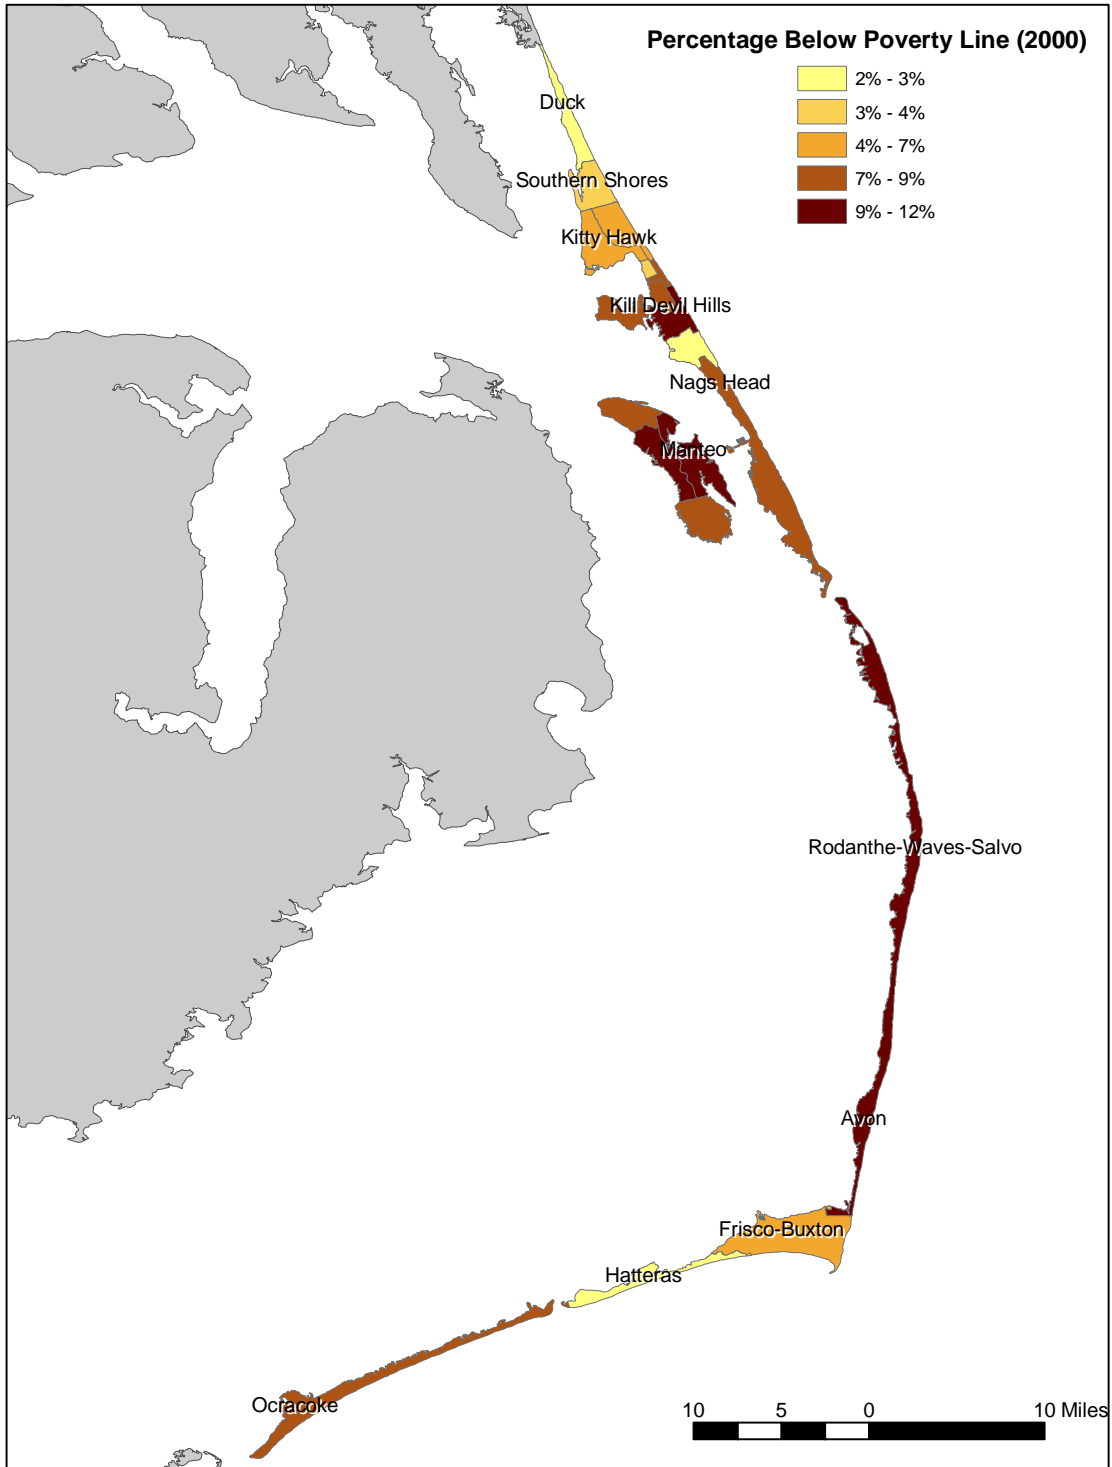

**FIGURE 28. 1999 PER CAPITA INCOME BY BLOCK GROUP**

In 2000, the ROI had a minority population of only 6% of the total (table 40). This is less than in North Carolina and the U.S. as a whole, which had 30% and 31% minority populations respectively. The ROI also had a lower percentage of individuals below the poverty level and a lower percentage of individuals without high school diplomas. The distribution of poverty rates by block groups is shown in figure 29.

**FIGURE 29. PERCENTAGE OF POPULATION BELOW THE POVERTY LINE BY BLOCK GROUP, 2000**

## EMPLOYMENT

As noted above, with the exception of the northern portion of Dare County, the ROI is primarily rural. There are no military bases, major federal facilities, state prisons, commercial airports, or four-year colleges in the ROI.

Within the ROI, much of the employment caters to tourists visiting the area. The sectors of construction; accommodation and food services; real estate, rental and leasing; and the retail trade accounted for 47.52% of the total employment within the ROI and 49.98% within the Hatteras block groups in 2000. These sectors only account for 26.50% of employment in the United States as a whole (table 39).

The majority of businesses within the ROI are located in the northern three zip codes of Dare County, encompassing the towns of Duck, Southern Shores, Kitty Hawk, Kill Devil Hills, and Nags Head. This area accounts for 64.8% of establishments and 69.6% of employment within the ROI in 2007 and has seen robust employment growth since 2000. Other areas of the ROI have experienced smaller gains or reductions in employment (figure 30). In 2007, Hatteras and Ocracoke islands contained 13.1% of the employees within the ROI. Small businesses are especially important within the ROI, with 1,713 of 2,104 establishments (81.42%) in the ROI operating with fewer than 10 employees in 2007, compared to 73.37% nationwide (Population Division, U.S. Census Bureau 2010).

In addition to these employees, Dare and Hyde counties had 5,470 of self-employed individuals in 2008. The construction, real estate, rental and leasing, and agriculture, forestry, fishing and hunting (of which 93% are commercial fishermen) industries comprise 47% of all nonemployers<sup>9</sup> in the two counties (table 41).

## UNEMPLOYMENT

In 2009 an average of 9.6% of the civilian labor force in Dare County was unemployed (2,179 individuals) and 8.3% in Hyde County (229 individuals, compared with an unemployment rate of 10.6% for North Carolina as a whole) (table 42).

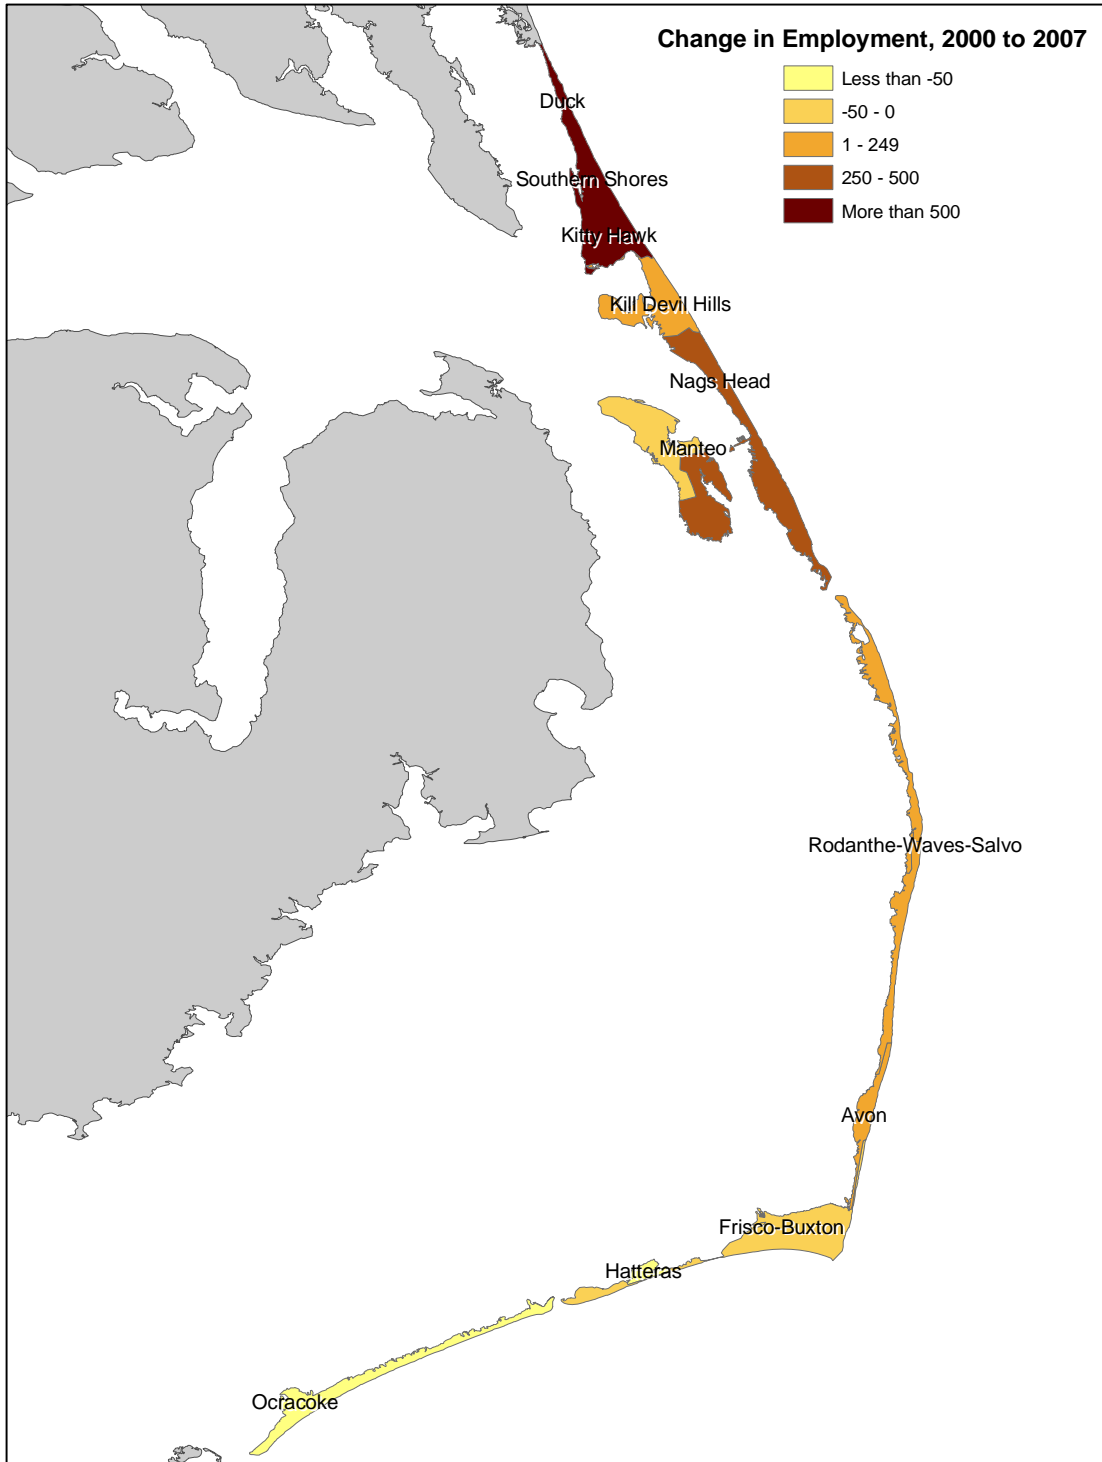

Within Dare County, establishments in construction, manufacturing, and retail trade industries accounted for 54% of private employment losses from 2007 to 2009. The retail trade and wholesale industries accounted for an additional 30% of private jobs. Within the retail trade, 53% of those job losses occurred in building material and garden equipment and supplies dealers and furniture and home furnishings stores. Sporting goods store employment declined 2.6% between 2007 and 2009 (Bureau of Labor Statistics 2010b).

In North Carolina, Dare and Hyde counties, and in the nation as a whole, unemployment rates began increasing in 2008 and continued to increase in 2009. Dare County's year-over-year unemployment change (change from the same month in the previous year) was greater than that for the state of North Carolina as a whole between November 2008 and March 2009 and lower than the state's unemployment change for the rest of 2009 (figure 31).

---

<sup>9</sup> From <http://www.census.gov/econ/nonemployer/intro.htm>: "Nonemployers are typically self-employed individuals operating very small businesses, which may or may not be the owner's principal source of income...Data are primarily comprised of sole proprietorship businesses filing IRS Form 1040, Schedule C, although some of the data is derived from filers of partnership and corporation tax returns that report no paid employees."

## 2000 UNEMPLOYMENT BY ZIP CODE

Using the 2000 census, one can calculate a measure of unemployment using information about labor force participation. Unemployment calculated with census data is somewhat different than the definition used by the Bureau of Labor Statistics. Within the ROI, the unemployment rate in 2000 varied between a low of 0% in the Waves and Frisco zip codes to a high of 21.6% in the Salvo zip code (table 42-1 and figure 31). The Employment Security Commission of North Carolina's Labor Market Information Division estimates zip code level unemployment data for 2010 by multiplying the current Bureau of Labor Statistics county unemployment estimate by the ratio of unemployment by zip code to unemployment within the entire county based on the 2000 census data. The differences in employment in 2000 does not provide information on how recent ORV regulations have impacted the ROI, but it does highlight how employment varied across the island in 2000.

**TABLE 42-1. LABOR FORCE AND UNEMPLOYMENT IN 2000 BY ZIP CODE**

Geographic Area	Zip Code	Labor Force	Unemployed	Unemployment Rate
Dare County		16,504	808	4.9%

## BUSINESS SURVEY

NPS contracted with RTI to conduct surveys of local businesses to provide additional information for the ORV planning process. The business survey (RTI 2010c) included questions about the characteristics and size of local businesses to assess the possible impacts of the action alternatives on revenue relative to the no-action alternatives, as discussed later in chapter 4. For the purposes of the survey, NPS divided businesses into two groups based on geographic location. The first group included businesses in the villages that directly border the Seashore, called the “Seashore villages” (Rodanthe, Waves, Salvo, Avon, Buxton, Frisco, Hatteras, and Ocracoke). These businesses depend heavily on tourists visiting the beaches on the Seashore. The second group included businesses located north of the Seashore boundary in the villages of Nags Head, Kill Devil Hills, and Kitty Hawk. These businesses serve tourists that visit the Seashore, but their customer base also includes visitors who use the beaches outside the Seashore on the Outer Banks.

Four primary industry categories were selected for interviewing: recreational supplies, rental homes, lodging excluding rental homes, and commercial fishermen. In addition to these four industry categories, several other industry categories serve tourists directly, which are addressed in the impact analysis (see chapter 4). These surveys all followed the same format, with appropriately worded questions for the

specific industries, and were administered by telephone. Up to 10 calls were made to each business if the number was busy or no one answered.

Businesses were first asked to provide general information describing their business, including services and products offered and seasons of operation. The second set of questions collected information on revenue and number of employees, including seasonal variation, to classify the size of businesses and characterize the business community in general. Next, businesses were asked to provide the change in revenue between 2007 and 2008 (which represent implementation of alternative A (2007) and alternative B (2008)). Finally, the survey requested the respondents' estimations of how different alternative management scenarios would affect their revenue. For the purposes of this survey, the two different alternative management scenarios generally represented the two action alternatives that contained elements from opposite ends of the management spectrum for elements of the action alternatives under consideration at the time. A question was also asked about the effects of closing soundside ramps to ORV use, but leaving them open to pedestrians (which represented the third scenario in the survey).

RTI conducted the surveys between June 1 and August 31, 2009. The timing of the surveys was dictated primarily by the schedule needed to meet the court-ordered deadline for finalizing the new rule and by the *Paperwork Reduction Act*, which requires Office of Management and Budget approval for information collection and public comment. Conducting the surveys over the summer ensured that seasonal businesses were available to participate; however, because business owners are busiest during the summer, the timing of the surveys made it difficult for some businesses to participate.

The overall response rate to the survey was 42%, although response rates varied depending on the business category and whether the business was located in one of the Seashore villages or in the villages just north of the Seashore. Businesses that responded to the survey were generally worried about the future impacts of the action alternatives. Many said they were already feeling the impacts, although they acknowledged that economic conditions and fuel prices in 2008 made it difficult to identify the impact of beach closures. Overall, the business survey provided the following general conclusions:

- All but eight of the businesses interviewed were categorized as small businesses based on Small Business Administration (SBA) definitions.
- Businesses north of the Seashore in Nags Head, Kill Devil Hills, and Kitty Hawk overall expected smaller impacts from any change in ORV management relative to the Seashore villages. The response rate from these businesses was lower, in part because the issue was not expected to have a big impact. However, some of the businesses that responded to the survey predicted significant drops in revenue from the two alternative management scenarios described in the survey.
- Businesses that rented vacation homes fared better between 2007 and 2008 than recreational supply and lodging businesses (lodging businesses are lodging that are not used for rental homes, for example, hotels).
- In all business categories, the majority of businesses reported that revenue fell between 2007 and 2008, but the majority also reported hiring the same number of full and part-time employees in 2007 and 2008.
- The majority of businesses thought that all alternative management scenarios described in the survey would result in decreased revenue compared to 2008. A smaller number expected no change or an increase.

- The alternative management scenario under which all the spits and points were closed year-round was expected to result in the biggest decrease in revenue.
- Fewer businesses felt comfortable providing a quantitative forecast of the expected impact of the alternative management scenarios on revenue given the uncertainties surrounding the cause of changes in revenue between 2007 and 2008, the impact of the alternatives on visitation, and the year-to-year variation in weather and species nesting patterns.
- From the businesses providing quantitative forecasts: Businesses forecast median decreases of 0% to 25% in annual revenue compared to 2008 for the alternative management scenario that would completely close the points and spits and a few miles of beach between ramp 27 (south of Salvo) and Buxton all year. For the second alternative, which did not involve the year-round closures of points and spits but would create ORV and pedestrian corridors to some popular spots (such as Bodie Island Spit, about a mile of the Cape Point area and the South Point area of Ocracoke) the median change in revenue compared to 2008 ranged from a decrease of 12% to no change. When asked about the potential impacts of closing the soundside ramps, survey respondents indicated median estimates of revenue loss ranging from no change to -4%.

### **TOURISM CONTRIBUTIONS TO THE ECONOMY**

The economy of the ROI is largely driven by the region's tourist draw, mainly during the summer months. As estimated by the North Carolina Department of Commerce, travel expenditures in Dare County have increased faster than those for the state as a whole (table 43); however, travel expenditures in Hyde County have decreased since 2000. In 2008, the Department of Commerce estimated that tourism was responsible for 11,250 jobs in Dare County and 370 jobs in Hyde County (North Carolina Department of Commerce 2009).

### **REGIONAL DISTRIBUTION OF TAX RECEIPTS WITHIN DARE COUNTY**

The Outer Banks Visitors Bureau posts monthly data on gross tax receipts from lodging and meals (Outer Banks Visitors Bureau 2010a and 2010b). Over the years, the county has made changes to the tax rate and the items that are taxed, so it is difficult to directly compare tax receipts across years. The data are provided for Dare County as a whole and the Seashore villages. Although year-to-year totals cannot be directly compared, assuming that taxes are consistent across the entire county, the percentage of tax receipts for all of Dare County generated by the Seashore villages provides one measure of how the tourism economy of the Seashore villages compares over time with the whole of Dare County. The Seashore villages contributed between 22% and 38% of the gross occupancy receipts in Dare County from March through November in the years 2006 through 2009 (figure 31-1). The Seashore village contribution is higher in the spring and fall, and has been consistent over the years. For gross meal receipts, however, the Seashore villages contribute between 8% and 15% of the receipts in Dare County, with their contribution higher in the summer. The gross meal receipts have also been consistent over the years (figure 31-2; table 43).

Geographic Area	1991	2000	2008	2000 to 2008 CAGR
North Carolina	\$11,092.58	\$15,089.89	\$16,864.60	1.6%
Dare County	\$377.40	\$624.14	\$777.41	3.2%
Hyde County	\$17.93	\$29.58	\$28.11	-0.7%

Source: North Carolina Department of Commerce 2009

**Housing**

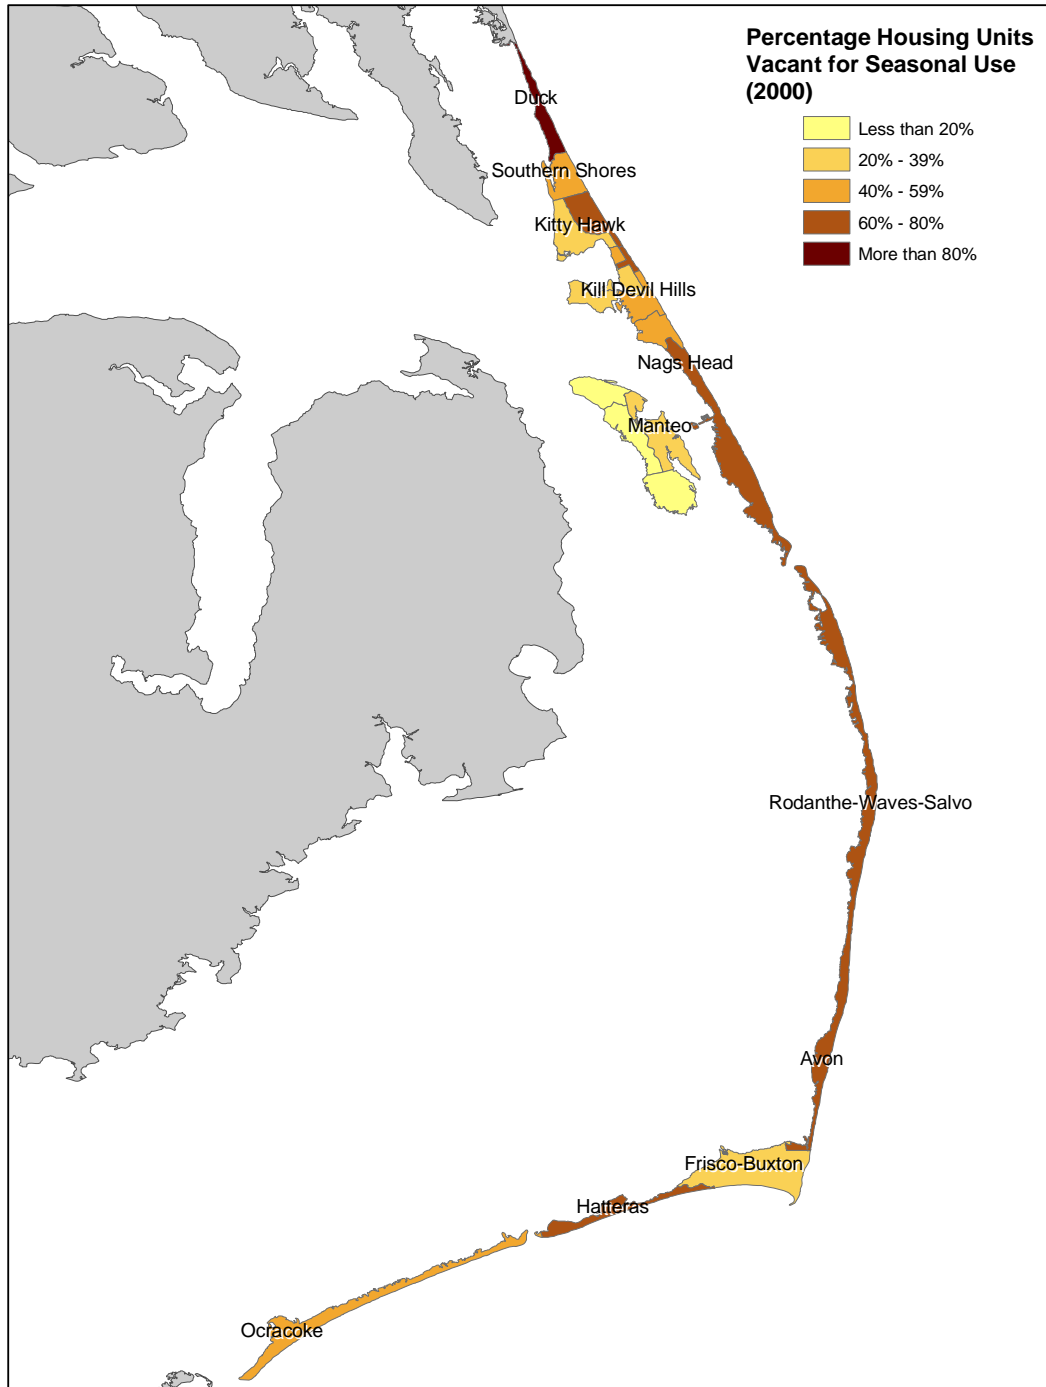

In 2000, the ROI had a total of 26,891 housing units, with 97% of these located in the Dare County block groups. The ROI’s housing is roughly 54% urban and 46% rural, with 100% of the urban housing units being located in Dare County block groups. Over 50% of the housing units in the ROI are for seasonal, recreational, or occasional use (table 44). The distribution of vacant housing units for seasonal, recreational, or occasional use is shown in figure 32. This is further evidence of the importance of tourism’s contributions to the region’s economy.

TABLE 44. HOUSING UNIT STATISTICS, 2000

	United States	North Carolina	ROI
Total	115,904,641	3,523,944	26,891

Source: U.S. Census Bureau 2000

**FIGURE 32. PERCENTAGE OF HOUSING UNITS VACANT FOR SEASONAL, RECREATIONAL, OR OCCASIONAL USE BY BLOCK GROUP, 2000**

Since 2000, Dare County has experienced a 21% increase in the number of housing units, relative to a 14% change state wide (table 45). However, in October of 2008, Dare County had the fifth highest foreclosure rate of any county in North Carolina, with one in every 679 housing units in foreclosure (RealtyTrac.com 2008).

**TABLE 45. CHANGE IN HOUSING UNITS**

Geographic Area	2000	2008	Percent Change 2000–2008
United States	115,904,641	129,065,264	11%
North Carolina	3,523,944	4,201,378	19%
Dare County	26,671	32,749	21%
Hyde County	3,302	3,495	5%

### Quality of Life

Quality of life encompasses those attributes of resources (man-made or naturally occurring) of a region that contribute to the well-being of its residents. The relative importance of these attributes to a person's well-being is subjective (e.g., some individuals consider outdoor recreational opportunities essential to their well-being, others require access to cultural institutions essential to their quality of life, and still others may hold public safety as their primary quality-of-life concern). Quality-of-life analyses typically address issues relating to potential impacts of the proposed action on the availability of public services and leisure activities that contribute to the quality of life of an affected ROI's inhabitants. For the purpose of this study, the quality-of-life affected environment includes the natural environment, public schools, law enforcement, medical facilities, and fire protection services.

The natural environment, including beaches and wildlife, provide the primary basis for quality of life on the Outer Banks. As discussed above, beach-related tourism drives the economy of the area. Local residents also receive significant recreational benefits from the area's natural assets. In addition to the Seashore, the ROI includes Jockey's Ridge State Park and Pea Island NWR (Outer Banks Chamber of Commerce 2008). There are also public beaches, marinas, piers, and other recreational outlets. Two categories of outdoor recreation pertinent to the assessment of alternative management plans, recreational fishing and bird watching, are discussed further below using data from the National Survey of Fishing, Hunting, and Wildlife-Associated Recreation.

### Fishing

North Carolina is the sixth most popular state for fishing, with an estimated 1,263,000 residents and nonresidents participating in 2006 (U.S. Census Bureau 2008b). Recreational fishing is a significant part of North Carolina's economy, attracting spending from both local and out-of-state anglers. Approximately 519,000 anglers in North Carolina engaged in saltwater fishing in 2006 (table 46). Expenditures from fishing trips totaled an estimated \$692,977,000 in 2006, with \$450,313,000 coming from saltwater anglers. While only 40% of anglers report participating in saltwater fishing, nearly 65% of all trip-related expenditures go toward this activity.

**TABLE 46. RECREATIONAL FISHING IN NORTH CAROLINA, BY RESIDENTS AND NONRESIDENTS**

	Resident	Nonresident	Total
Total participants	868,000	395,000	1,263,000
% Total participants	69%	31%	100%
# Saltwater	253,000	266,000	519,000
% Saltwater	49%	51%	100%
Total trip-related expenditures	\$395,296,000	\$297,681,000	\$692,977,000
Average trip-related expenditures per participant	\$456	\$753	\$549

Source: U.S. Census Bureau 2008b

Nonresident angler expenditures are important to regional economic impacts, as they represent an addition to area wealth rather than a change in the mix of spending by residents. Nonresidents make up only 31% of all anglers in North Carolina but comprise 51% of saltwater anglers. Nonresidents, who often must pay greater lodging and transportation fees, spend an average of 65% more than residents for trip-related expenditures over all types of fishing.

Separate expenditure data for residents and nonresidents on saltwater fishing were not available. However, trip-related expenditures (including food, lodging, transportation, ice, bait, guide and usage fees, rental equipment, and other items, but excluding the cost of purchased equipment) are much higher for saltwater anglers than for all anglers combined, averaging \$754 per person for both residents and nonresidents, compared to \$549 per person for all fishing. Saltwater fishermen spend more per angler on food and lodging, transportation, and other trip costs, but spend proportionally less on transportation and slightly more on food, lodging, and other costs. Overall, saltwater fishing such as that on Cape Hatteras attracted a greater percentage of out-of-state residents and averaged 56% greater trip-related expenditures than all types of fishing combined.

Dare and Hyde counties sold 40% of coastal recreational fishing licenses sold within the eight coastal counties in North Carolina and 18% of all coastal recreational fishing licenses sold in 2008. Dare County ranks first among all North Carolina counties in coastal recreational fishing license sales (table 47).

**TABLE 47. NUMBER OF COASTAL RECREATIONAL FISHING LICENSES SOLD BY NORTH CAROLINA COUNTY OF SALE (LOCATION WHERE LICENSE SALES AGENT RESIDES), EXCLUDING BLANKET COASTAL RECREATIONAL FISHING LICENSES, BY CALENDAR YEAR**

County	2007	2008
Dare	93,225	82,635
Hyde	6,322	5,358
Brunswick	38,721	33,303
Carteret	46,813	38,456
Currituck	2,660	2,435
New Hanover	34,556	28,558
Onslow	16,098	15,185
Pender	17,462	14,733
Total	469,521	411,886

Source: NCWRC 2008a

## Wildlife Watching

Among all states, North Carolina ranks nineteenth for number of wildlife watchers, with 2,641,000 participants in 2006. Wildlife watching is classified as activities for which wildlife watching is the primary purpose, and does not include trips to zoos or museums or accidental observation of wildlife. Wildlife watchers may be feeding, photographing, or observing wildlife. Approximately 15% of wildlife watchers in North Carolina were nonresidents in 2006.

Away-from-home wildlife watching is defined as wildlife observation occurring at least one mile away from home. Table 48 presents information about away-from-home wildlife watching in North Carolina. Among away-from-home wildlife watchers in North Carolina, approximately 56% are nonresidents. Away-from-home bird watchers made up 620,000 or 90% of all away-from-home wildlife watchers. Of these, 50% reported watching “other waterbirds.” This category includes shorebirds, cranes, herons, and all other waterbirds not classified as waterfowl and serves as the best representation of birds on Cape Hatteras. Among wildlife watchers observing “other waterbirds,” nonresidents made up 69% of participants. Thus, wildlife watching for birds like those on Cape Hatteras is far more likely to be participated in by nonresidents than other wildlife watching.

**TABLE 48. AWAY-FROM-HOME WILDLIFE WATCHING IN NORTH CAROLINA, BY RESIDENT AND NONRESIDENT**

	Resident	Nonresident	Total
Total away-from-home participants	300,000	386,000	686,000
Percent of total participants	44%	56%	100%
Total away-from-home birders	284,000	336,000	620,000
Total birders	46%	54%	100%
Away-from-home “other waterbird” observers	95,000	215,000	310,000
Percent of “other waterbird” observers	31%	69%	100%
Total trip-related expenditures	\$84,245,000	\$162,662,000	\$246,906,000
Average trip-related expenditure per participant	\$281	\$421	\$360

Source: U.S. Census Bureau 2008b

Wildlife watchers in North Carolina spent a total of \$246,906,000 in trip-related costs in 2006. This number includes food, lodging, transportation, rented equipment, and guide or permit fees, but not expenditures on purchased equipment. Away-from-home resident wildlife watchers spent an average of \$281 per person per trip, while nonresident participants spent \$421. Although separate expenditure data for other waterbird watchers were not available, other waterbirds such as shorebirds are more likely to attract out-of-state wildlife watchers, who then spend on average 50% more than resident wildlife watchers.

## Preservation and Nonuse Values

Preservation or nonuse impacts represent a category of values held by people independent of their use of the resources that also includes existence value and bequest value. The main assumption underlying the concept of nonuse values is that individuals’ welfare can be enhanced simply by the *knowledge* that specific ecosystems are being protected or improved. As the name implies, individuals receive these types

of services without any specific use of or interaction with the ecosystems. For example, nonuse values from preserving a natural area may come from the knowledge that future generations are more likely to experience and enjoy the area (i.e., “bequest values”).

Economic theory recognizes that individuals can hold value for the Cape Hatteras National Seashore and the ecosystems contained within its boundaries because they want future generations to enjoy the area, because they value the protected species supported by the area, or because they feel the natural communities contained within the National Seashore have intrinsic value separate from the value they provide to visitors.

Measuring values for these “nonuse” services is more difficult and involves more uncertainty than for recreational and aesthetic services. Nevertheless, a variety of studies demonstrate that nonuse values exist and may be quite large depending on the resource in question. Loomis and White (1996) synthesized key results from 20 threatened and endangered species valuation studies using meta-analysis methods. They were able to identify variables that explain the observed variation in estimated willingness-to-pay (WTP) values for threatened and endangered species and examine how per-household benefit estimates compare with cost estimates for protection. In their meta-analysis, Loomis and White reviewed 20 contingent value studies coming from both the published and gray literature. They found that annual WTP estimates range from a low of \$8 for the Striped Shiner fish to a high of \$124 for the Northern Spotted Owl. Using these 20 studies, they applied regression based methods to combine valuation findings and to identify statistically significant determinants of estimated values for threatened and endangered species. Some of their key findings include statistically significant effects on WTP of (1) the size of the change in a species population; (2) whether those expressing values for the species are users of the affected resource; and (3) whether the species is a marine mammal or bird. Loomis and White also used the meta-analysis results to conduct a rough benefit-cost analysis. They noted that even in supposedly “high cost” cases, such as the Northern Spotted Owl, costs per household are relatively low and are well below the benefits found in WTP studies.

## SEASHORE OPERATIONS AND MANAGEMENT

Management of ORV use at the Seashore, and implementation of the related administrative activities and field operations, involves all five NPS operational divisions, as well as the Superintendent’s Office (Park Management). The baseline for Seashore operations and management will be discussed both in terms of pre-consent decree (under the Interim Strategy) (before 2008) and post-consent decree (2008).

**Management and Administration.** Management and administrative staff members at the Seashore have a variety of responsibilities related to ORV management, including compiling and sending out weekly access and resource updates, managing payroll for the Seashore, fielding questions from visitors regarding ORV management, fulfilling human resources functions and supervisory roles, and providing information technology and other technical support, in addition to the superintendent’s role in ORV management. Administrative costs address the need to provide technical assistance to the approximately 25 field and administrative staff members associated with ORV management. Administrative support related to ORV management required approximately 4.75 full-time equivalent (FTE) (\$428,750) under the Interim Strategy. This number increased to 5.35 (\$480,950) plus approximately \$3,000 of direct materials costs (total cost \$483,950) in 2008 with the implementation of measures under the consent decree. The increased level of effort for administration is primarily related to the increased need for information technology support as the use of technology was increased to inform the public about areas open for ORV use or closed for species protection.

**Visitor Protection.** Law enforcement officers at the Seashore are responsible for enforcing all applicable regulations, including those related to ORV and species management. In relation to ORV management,

duties of law enforcement include patrolling the Seashore, as well as providing on-the-spot interpretation to visitors as to the reason for certain ORV regulations and species management efforts. Other duties include responding to violations and conducting investigations. Support (or materials) costs for these Seashore staff members include vehicles, fuel, training, travel, field supplies, and radio support. Visitor protection support related to ORV management required approximately 13 FTE (\$1,047,500) and \$100,000 in support costs (total cost approximately \$1,147,500) under the Interim Strategy. This number increased to 16.5 FTE (\$1,321,500) and \$160,000 in support costs (total cost approximately \$1,481,000) in 2008 with the implementation of measures under the consent decree. This increased level of effort for law enforcement is primarily related to the increased amount of time patrol rangers are devoting to ORV management, such as addressing the night-driving restrictions under the consent decree.

**Resources Management.** Resources management staff members at the Seashore are responsible for all monitoring and surveying of species at the Seashore, as well as establishing and changing the required resource closures once state- or federally listed species are found at the Seashore. This staff includes supervisory roles as well as full- and part-time field staff to implement species management measures. Support (or materials) costs for these Seashore staff members include vehicles (such as four-wheel drive vehicles, ATVs/Utility Terrain Vehicles [UTVs]), fuel, training, field supplies (such as signs, string, flagging, and rope), monitoring supplies, and travel. Resources management efforts at the Seashore required approximately 9.5 FTE (\$423,500) and \$85,000 in support costs (total cost approximately \$508,500) under the Interim Strategy. This number increased to 15 FTE (\$778,000) and \$35,000 in support costs (total cost approximately \$813,000) in 2008 with the implementation of measures under the consent decree. This increased level of effort for resource management staff is primarily related to the need for additional field staff and Geographic Information Systems (GIS) staff to address the closure requirements and to be able to provide weekly reports and mapping of the closures to keep the public informed of their activities. Resources management staff is also responsible for preparation of all required annual reports for protected species, research on protected species or factors that affect the species, predator control activities, and coordination of regulatory and scientific activities with other entities such as the USFWS and NCWRC.

**Interpretation.** Interpretation staff members at the Seashore are responsible for providing information programs to Seashore visitors, specifically on the subject of species management. Support (or materials) costs for these Seashore staff include printing newsletters and brochures, and obtaining materials for visitor programs. Interpretation efforts at the Seashore required approximately 1.5 FTE (\$58,500) and \$10,000 in support costs (total cost approximately \$68,500) under the Interim Strategy. This number increased to 3.0 FTE (\$181,500) and \$12,000 in support costs (total cost approximately \$193,000) in 2008 with the implementation of measures under the consent decree. This increased level of effort for interpretation staff is primarily related to the increased level of programs and information provided to the public regarding areas available for ORV use, as well as providing information about why certain ORV and species management measures are being implemented at the Seashore. With the increase in programs, the number of staff members devoted to ORV management issues has also increased.

**Facility Management.** Facility management staff members at the Seashore are responsible for providing maintenance and repairs for beach ramps and parking lots, as well as installation of informational signs along the beach. This division of the Seashore is also responsible for maintaining and repairing the vehicles used by all other divisions of the Seashore, including those used for law enforcement and resource management patrols. Support (or materials) costs for these Seashore staff members include ramp fill material, vehicle parts, and vehicle maintenance supplies. Facility management efforts required approximately 0.6 FTE (\$46,500) and \$10,000 in support costs (total cost approximately 56,500) under the Interim Strategy. This number increased to 3.6 FTE (\$158,600) and \$20,000 in support costs (total cost approximately \$178,600) in 2008 under the implementation of the consent decree. This increased level of effort for facility management staff is primarily related to the need to increase the number of

Chapter 3: Affected Environment

maintenance workers and laborers. The increase in both law enforcement and resource management staff results in an increased number of vehicles that need to be maintained. The additional signage and educational requirements require more staff and effort to install, and an increased level of effort.

## CHAPTER 4: ENVIRONMENTAL CONSEQUENCES

This “Environmental Consequences” chapter analyzes both beneficial and adverse impacts that would result from implementing any of the alternatives considered in this long-term ORV plan/EIS. This chapter also includes a summary of laws and policies relevant to each impact topic, definitions of impact thresholds (e.g., negligible, minor, moderate, and major), methods used to analyze impacts, and the analysis methods used for determining cumulative impacts. As required by the CEQ regulations implementing NEPA, a summary of the environmental consequences for each alternative is provided in table 13, which can be found at the end of chapter 2. The resource topics presented in this chapter, and the organization of the topics, correspond to the resource discussions contained in “Chapter 3: Affected Environment.”

### SUMMARY OF LAWS AND POLICIES

Three overarching environmental protection laws and their implementing policies guide the actions of the NPS in the management of the parks and their resources—the *Organic Act of 1916*, NEPA and its implementing regulations, and NPOMA. For a complete discussion of these and other guiding authorities, refer to the section titled “Related Laws, Policies, Plans, and Constraints” in “Chapter 1: Purpose of and Need for Action.” These guiding authorities are briefly described below.

The *Organic Act of 1916* (16 USC 1), as amended and supplemented, commits the NPS to making informed decisions that perpetuate the conservation and protection of park resources, leaving them unimpaired for the benefit and enjoyment of future generations.

NEPA is implemented through regulations of the CEQ (40 CFR 1500–1508). The NPS has, in turn, adopted procedures to comply with these requirements, as found in Director’s Order 12 (NPS 2001a) and its accompanying handbook.

NPOMA (16 USC 5901 et seq.) underscores the NEPA provisions in that both acts are fundamental to park management decisions. Both acts provide direction for connecting resource management decisions to the analysis of impacts and communicating the impacts of those decisions to the public, using appropriate technical and scientific information. Both acts also recognize that such data may not be readily available, and they provide options for resource impact analysis should this be the case.

Section 4.5 of Director’s Order 12 adds to this guidance by stating, “when it is not possible to modify alternatives to eliminate an activity with unknown or uncertain potential impacts, and such information is essential to making a well-reasoned decision, the National Park Service will follow the provisions of the CEQ regulations (40 CFR 1502.22).” In summary, the NPS must state in an environmental assessment or impact statement (1) whether such information is incomplete or unavailable; (2) the relevance of the incomplete or unavailable information to evaluating reasonably foreseeable significant adverse impacts on the human environment; (3) a summary of existing credible scientific adverse impacts that is relevant to evaluating the reasonably foreseeable significant adverse impacts; and (4) an evaluation of such impacts based on theoretical approaches or research methods generally accepted in the scientific community. Collectively, these guiding regulations provide a framework and process for evaluating the impacts of the alternatives considered in this plan/EIS.

## **GENERAL METHODOLOGY FOR ESTABLISHING IMPACT THRESHOLDS AND MEASURING EFFECTS BY RESOURCE**

The following elements were used in the general approach for establishing impact thresholds and measuring the effects of the alternatives on each resource category:

- General analysis methods as described in guiding regulations, including the context and duration of environmental effects.
- Basic assumptions used to formulate the specific methods used in this analysis.
- Thresholds used to define the level of impact resulting from each alternative.
- Methods used to evaluate the cumulative impacts of each alternative in combination with unrelated factors or actions affecting Seashore resources.
- Methods and thresholds used to determine if impairment of specific resources would occur under any alternative.

These elements are described in the following sections.

### **GENERAL ANALYSIS METHODS**

The analysis of impacts follows CEQ guidelines and Director's Order 12 procedures (NPS 2001a) and incorporates the best available scientific literature applicable to the region and setting, the resource evaluated, and the actions considered in the alternatives.

For each resource topic addressed in this chapter, the applicable analysis methods are discussed, including assumptions and impact intensity thresholds.

### **ASSUMPTIONS**

#### **Duration and Type of Impacts**

The following assumptions are used for all impact topics (the terms "impact" and "effect" are used interchangeably throughout this document):

- **Short-term:** Impacts are temporary (i.e., they occur for a matter of hours up to weeks at a time) without lasting effects. Examples include impacts from the ability of a visitor to access a certain area during a resource closure event.
- **Long-term:** Impacts are continuous throughout the life of the plan, with potentially permanent effects. Examples include ongoing impacts to Seashore management and operations.
- **Direct:** Impacts would occur as a direct result of ORV management actions.
- **Indirect:** Impacts would occur from ORV management actions but would occur later in time or farther in distance from the action.
- **Beneficial:** A positive change in the condition or appearance of the resource or a change that moves the resource toward a desired condition.
- **Adverse:** A change that moves the resource away from a desired condition or detracts from its appearance or condition.

## Impacts of Climate Change

Studies predict that coastal barrier islands and their natural and cultural resources will be affected by sea level rise and potentially stronger storm events resulting from climate change. Relative sea level is currently rising in northeastern North Carolina at a rate of 16 to 18 inches per century, a substantially higher rate than the 7 inches per century one hundred years ago and the 3 inches per century rate 200 years ago. The current rate will likely continue to increase into the future as the climate continues to warm (Riggs et al. 2008). Various alternatives for human adaptation to changing conditions on the barrier islands have been proposed (Riggs et al. 2008), but much of government, business, organization and individual response to the challenges of climate change is undetermined. Future threats of deterioration, segmentation, and collapse of the barrier islands along the North Carolina Outer Banks coast as a result of increased sea-level rise and storm activity have been described (Culver et al. 2007, 2008; Riggs and Ames 2003; Riggs et al. 2009). Given the complex interactions among multiple factors and the uncertainties over human response to climate change on the barrier islands, the level of uncertainty about possible effects on specific resources or impact topics over the 10–15 year planning period makes analysis for impacts of climate change in this document speculative. It is assumed that management that would build resiliency into the Seashore's wildlife and plant resources (e.g., management measures to allow increases in populations of protected species during the next 10–15 years) would be beneficial to those resources as they adapt to changed conditions over future decades.

## Impact Thresholds

Determining impact thresholds is a key component in applying NPS *Management Policies 2006* and Director's Order 12. These thresholds provide the reader with an idea of the intensity of a given impact on a specific topic. The impact threshold is determined primarily by comparing the effect to a relevant standard based on applicable or relevant/appropriate regulations or guidance, scientific literature and research, or best professional judgment. Because definitions of intensity vary by impact topic, intensity definitions are provided separately for each impact topic analyzed in this document. Intensity definitions are provided throughout the analysis for negligible, minor, moderate, and major impacts. Except for the threatened and endangered species topic, the impact thresholds are defined for adverse impacts, and beneficial impacts are addressed qualitatively. For endangered and threatened species, both beneficial and adverse impacts are qualified to facilitate Section 7 compliance.

## CUMULATIVE IMPACTS

The CEQ regulations to implement NEPA require the assessment of cumulative impacts in the decision-making process for federal projects. Cumulative impacts are defined as “the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal or nonfederal) or person undertakes such other actions” (40 CFR 1508.7). Cumulative impacts are considered for all alternatives, including the no-action alternatives.

Cumulative impacts were determined by combining the impacts of the alternative being considered with other past, present, and reasonably foreseeable future actions. Therefore, it was necessary to identify other ongoing or reasonably foreseeable future projects and plans at the Seashore and, if applicable, the surrounding region. Table 49 summarizes the actions that could affect the various resources at the Seashore. These actions are described in more detail in the “Related Policies, Laws, Plans, and Actions” section of this document (see “Chapter 1: Purpose of and Need for Action”). Recreational use, past, present, and future, is considered as an integral part of the action alternatives and is, therefore, not addressed within the cumulative impact scenario.

The analysis of cumulative effects was accomplished using four steps:

Step 1—Resources Affected. Fully identify resources affected by any of the alternatives.

Step 2—Boundaries. Identify an appropriate spatial and temporal boundary for each resource.

Step 3—Cumulative Action Scenario. Determine which actions to include with each resource.

Step 4—Cumulative Impact Analysis. Summarize the cumulative impact of the proposed action plus the other actions affecting the resource in question, defining context, intensity, duration and timing; defining thresholds, methodology, etc.

**TABLE 49. CUMULATIVE IMPACT SCENARIO**

Impact Topic	Study Area	Past Actions	Present Actions	Future Actions (life of plan/EIS)
Wetlands and floodplains	Seashore boundary, plus adjacent non-NPS lands on Bodie, Hatteras, and Ocracoke islands	Oregon Inlet dredging Storms and other weather events County Land Use Development Plan for Dare and Hyde counties Hurricane recovery Resource Management Plan Berm construction under the CCC and subsequent maintenance Continued maintenance of NC-12 and berms	Same as past actions	Same as present actions, plus NC-12 improvements on Bodie Island Bonner Bridge replacement
Federally listed threatened, or endangered species	Specific to species as identified in USFWS recovery plans (piping plover, sea turtles) or based on habitat range (seabeach amaranth)	Oregon Inlet dredging Storms and other weather events County Land Use Development Plan for Dare and Hyde counties Hurricane recovery Resource Management Plan Berm construction under the CCC and subsequent maintenance Continued maintenance of NC-12 and berms Long-range Interpretive Plan Previous attempts to complete ORV plans Concession permits/operations Species research efforts USFWS species recovery plans Commercial fishing Species management at Cape Lookout National Seashore	Same as past actions, plus Predator Management Plan (under development) Species management at Cape Lookout National Seashore, including implementation of the Interim Protected Species Management Plan/EA	Same as present actions, plus NC-12 improvements on Bodie Island Bonner Bridge replacement Development of Cape Lookout National Seashore ORV Management Plan/EIS Revision of the Cape Hatteras General Management Plan Revision of the Land Use Development Plan for Dare County

Impact Topic	Study Area	Past Actions	Present Actions	Future Actions (life of plan/EIS)
State-listed or special status species	North Carolina populations	Same as rare, unique, threatened, or endangered species	Same as rare, unique, threatened, or endangered species	Same as rare, unique, threatened, or endangered species
Wildlife and wildlife habitat (birds, invertebrates)	Seashore boundary, plus adjacent non-NPS lands on Bodie, Hatteras, and Ocracoke islands	Same as rare, unique, threatened, or endangered species	Same as rare, unique, threatened, or endangered species	Same as rare, unique, threatened, or endangered species
Soundscapes	Seashore boundary	Oregon Inlet dredging Storms and other weather events Continued maintenance of NC-12 and berms	Same as past actions, plus Increased vehicle traffic and village events Designation of Outer Banks Scenic Byway	Same as present actions, plus: Bonner Bridge replacement NC-12 improvements on Bodie Island Potential for military training operations, overflights
Visitor use and experience	Seashore boundary	Oregon Inlet dredging Storms and other weather events Hurricane recovery Resource Management Plan Previous attempts to complete ORV plans Continued maintenance of NC-12 and berms General Management Plan Long-Range Interpretive Plan Commercial fishing	Same as past actions, plus: Predator Management Plan (under development) Designation of Outer Banks Scenic Byway	Same as present actions, plus NC-12 improvements on Bodie Island Bonner Bridge replacement Development of Cape Lookout National Seashore ORV Management Plan/EIS Revision of the Cape Hatteras General Management Plan Revision of Land Use Development Plan for Dare County
Socioeconomic resources including local commercial fishing activities	Regional—counties	Storms and other weather events Commercial fishing Continued maintenance of NC-12 and berms	Same as past actions, plus: Designation of Outer Banks Scenic Byway	Same as present actions, plus: Development of Cape Lookout National Seashore ORV Management Plan/EIS Revision of Land Use Development Plan for Dare County

Impact Topic	Study Area	Past Actions	Present Actions	Future Actions (life of plan/EIS)
Seashore management and operations	All NPS facilities and lands managed by the Outer Banks Group	Oregon Inlet dredging Storms and other weather events Hurricane recovery Resource Management Plan General Management Plan Long-range Interpretive Plan Commercial fishing Continued maintenance of NC-12 and berms	Same as past actions, plus Ongoing law enforcement (note related to species or ORV management) Ongoing research studies Ongoing maintenance Ongoing surveying Predator Management Plan (under development)	Same as present actions, plus NC-12 improvements on Bodie Island Revision of the General Management Plan

## IMPAIRMENT ANALYSIS METHOD

Chapter 1 describes the related federal acts and policies regarding the prohibition against impairing Seashore resources and values in units of the national park system. According to *NPS Management Policies 2006*, an action constitutes an impairment when an impact “would harm the integrity of park resources or values, including the opportunities that otherwise would be present for the enjoyment of those resources or values” (NPS 2006c, sec. 1.4.5). To determine impairment, the NPS must evaluate “the particular resources and values that would be affected; the severity, duration, and timing of the impact; the direct and indirect effects of the impact; and the cumulative effects of the impact in question and other impacts” (NPS 2006c, sec. 1.4.5).

Since publication of the Cape Hatteras National Seashore Off-Road Vehicle Management Plan/Draft Environmental Impact Statement in March 2010, the NPS has issued Interim Guidance for Impairment Determinations in NPS NEPA Documents (Interim Guidance) (NPS 2010h). Consistent with the Interim Guidance, the draft written impairment determination only for the preferred alternative is included in appendix E of the final EIS.

On rare occasions, the no-action alternative, if continued may result in impairment. When this is the case, the fact that the no-action alternative will result in impairment should be discussed in the impact analysis for the no-action alternative. Therefore for this FEIS an impairment discussion is provided at the end of the impact analysis for alternative A for the following resources: sea turtles (in the “Federally Listed Threatened or Endangered Species” section), common tern, gull-billed tern and black skimmer (in the “State-Listed and Special Status Species” section). The content of the impairment determination for alternative A for these species has been revised in this final EIS to reflect the Interim Guidance.

## WETLANDS AND FLOODPLAINS

### GUIDING REGULATIONS AND POLICIES

Impacts on wetlands and floodplains are addressed under two federal executive orders: Executive Order 11990, Protection of Wetlands, and Executive Order 11988, Floodplain Management. NPS Director’s Order 77-1 establishes policies, requirements, and standards for implementing Executive Order 11990 for wetlands, while NPS Director’s Order 77-2 applies to all NPS-proposed actions that could adversely

affect the natural resources and functions of floodplains, including coastal floodplains, or increase flood risks.

According to Director's Order 77-1 and accompanying Procedural Manual 77-1, direct or indirect adverse impacts on wetlands should be avoided, or where impacts cannot be avoided, degradation or loss must be minimized by every practicable effort. The order adopts a "no net loss of wetlands" policy and states that the NPS will use the Cowardin classification system as the standard for defining wetlands for purposes of compliance with Executive Order 11990, which means that non-vegetated shorelines and mudflats are included in the wetlands classification. Any NPS activities that involve the discharge of dredged or fill materials into wetlands or "other waters of the United States" must also comply with the *Clean Water Act* and Section 404 regulations (33 CFR 1344) and Section 10 of the *Rivers and Harbors Act* (33 CFR 403), which prohibits the unauthorized obstruction or alteration of navigable waters of the United States.

If adverse impacts to wetlands would occur from a proposed project, a Statement of Findings is prepared, unless the actions are exempted for the various reasons provided in Procedural Manual 77-1, Section 4.2(A). Exceptions may include actions designed for restoring wetlands and water dependent actions that have minor impacts. As described more fully in the impact analysis, the rebuilding or expansion of any parking areas or access roads under any action alternative would be limited to developed or non-wetland areas, thereby avoiding impacts to wetlands. Indirect impacts may include minor effects from runoff to nearby wetlands. Impacts related to the management or improvement of access for ORVs would not require a Statement of Findings as long as new areas are not opened up for ORV use in wetland areas (Green and Noon pers. comm. 2008), although impacts related to this use are addressed in this section of the EIS. For these reasons, and as further detailed under the impact analysis, a Statement of Findings for wetlands was not required for this project.

Director's Order 77-2 states that when it is not practicable to locate or relocate development or inappropriate human activities to a site outside of and not affecting the floodplain, the NPS will prepare and approve a Statement of Findings, in accordance with procedures described in Procedural Manual 77-2, Floodplain Management, and take all reasonable actions to minimize the impact to the natural resources of floodplains. Because the study area is located entirely within a floodplain, and the action alternatives include construction of additional parking areas (or expansion of existing parking areas) and access in the floodplain, the NPS prepared a Statement of Findings for the preferred alternative (alternative F) in accordance with procedures described in Procedural Manual 77-2 (see appendix B for the Statement of Findings).

*NPS Management Policies 2006* also specifically address wetlands and floodplains in Sections 4.6.5 and 4.6.4, respectively. Section 4.6.5 refers to compliance with Executive Order 11990 and states that, when practicable, the NPS will not simply protect but will also seek to enhance wetland values. For any proposed new development or other activities that could adversely impact wetlands, the NPS will first avoid impacts, then minimize impacts, and then compensate for impacts on at least a one-to-one basis. Section 4.6.4 states that the NPS will protect, preserve, and restore the natural resource function of floodplains, avoid the long- and short-term environmental effects associated with the occupancy and modification of floodplains, and avoid floodplain development that could cause adverse impacts or flood risks.

## **ASSUMPTIONS, METHODOLOGY, AND IMPACT THRESHOLDS**

To assess the magnitude of impacts to Seashore wetlands and floodplains under the various alternatives, wetland types and floodplain boundaries were identified as needed for impact analysis, based on the sources described in "Chapter 3: Affected Environment." Actions under each alternative were considered and impacts were assessed by examining the types of uses and impacts that could occur in or near various

wetlands or in floodplains, examining the area that could be directly or indirectly affected by the proposed development of parking and access, and assessing impacts on wetland and floodplain functions and values using best professional judgment, input from NPS staff and EIS team members, and a review of relevant literature.

## WETLANDS

### Impact Thresholds

The impact thresholds for wetlands are based on the size, integrity, and connectivity of the wetlands affected. These indicators are defined as follows:

**Size.** The severity of impacts to wetlands depends on the size of the wetland impacted. A small area of impact in a large wetland would be likely to have less of an effect than a large area of impact in a small wetland. The change in the size of a wetland, as a result of an impact, would also influence the integrity and connectivity of the wetland.

**Integrity.** Highly intact wetland areas with little prior disturbance would be more susceptible to impacts from direct development than a wetland previously degraded by development or other activities. The loss of function and productivity of the higher quality wetland would be a greater loss than that of a lower quality wetland. Additionally, indirect impacts due to human trampling or a change in vegetation or hydrology would also impact the integrity of the wetland.

**Connectivity.** The relationship of wetlands to other wetlands or other valuable natural resources is also important in determining the degree of impact. Plant communities that are isolated from each other are less productive and functional than those that are connected. For example, narrow, previous trail corridors that are infrequently or seasonally used would have less fragmenting effect than would a wide hard-surface roadway with high volumes of vehicular or pedestrian traffic. Establishment of structures in wetland areas could also create barriers to the natural dispersal of plants and animals and impact the connectivity of wetlands.

A summary of wetland impacts under all alternatives is provided in table 50 at the end of this section. The following thresholds for evaluating impacts to wetlands were defined.

*Negligible:* No measurable or perceptible effects on size, integrity, or connectivity of wetlands would occur.

*Minor:* The effect on wetlands would be measurable or perceptible, but small in terms of area and the nature of the impact. A small effect on size, integrity, or connectivity would occur; however, the overall viability would not be affected. If left alone, an adversely affected wetland would recover, and the impact would be reversed.

*Moderate:* The impact would cause a measurable effect on one of the three wetlands indicators (size, integrity, connectivity) or would result in a permanent loss or gain in wetland acreage, but not to large areas. Wetland functions would not be affected in the long term.

*Major:* The impact would cause a measurable effect on all three wetlands indicators (size, integrity, connectivity) or a permanent loss or gain of large wetland areas. The impact would be substantial and highly noticeable. The character of the wetland would be changed so that the functions typically provided by the wetland would be substantially altered.

*Duration:* Short-term effects for vegetative wetlands: recovers in less than three years from any action taken.

Long-term effects for vegetative wetlands: takes longer than three years to recover, or effect is almost permanent.

Short-term effects for non-vegetated wetlands (shorelines): recovers within days to months.

Long-term effects for non-vegetated wetlands (shorelines): effects last longer than a few months.

## Study Area

The study area for assessment of the various alternatives is the Seashore. The study area for the cumulative impacts analysis is the Seashore plus the adjacent lands outside of the Seashore boundaries on Bodie, Hatteras, and Ocracoke islands.

## Impacts Common to All Alternatives

**Non-vegetated marine wetlands.** Non-vegetated marine intertidal wetlands are located at the Seashore between extreme high tide and extreme low tide. Each alternative provides for some ORV access (whether for surveying and management or recreational use) in varying areas of the Seashore according to where an ORV corridor is provided. The ORV corridor generally occurs approximately 150 feet landward of the average, normal high tide line, or if less than 150 feet of space is available, at the vegetation or the toe of the remnant dune line. This width may vary among alternatives, dependent on sensitive species location, but generally stays the same.

Impacts to wetland areas where ORVs are used include rutting and compaction of soils from ORV use by visitors or by staff during species management activities; however, due to the dynamic nature of the intertidal area, impacts would be expected to be short-term negligible adverse. These impacts would be short-term due to the continuous movement and deposition of sand in the intertidal areas and the ability of the shoreline to “restore” itself in the long term. Due to the nature of the impacts and the consistent regeneration of wetland soils impacted by ORV use due to wave action, impacts on marine intertidal wetlands are not discussed in detail under each alternative below; rather, it was assumed that impacts from ORV driving to non-vegetated marine intertidal wetlands would be short-term negligible adverse across all alternatives. The impact analysis therefore focuses on impacts to vegetated estuarine (soundside and interior) wetlands and addresses impacts to marine intertidal wetlands in the conclusions only.

Impacts to marine wetland habitats also affect invertebrate species that reside there, and are discussed in detail in the “Wildlife and Wildlife Habitat” section.

### **Impacts of Alternative A: No Action—Continuation of Management under the Interim Protected Species Management Strategy**

Under alternative A, there would be no new construction of ramps or roads and, therefore, no direct adverse impacts to wetlands in the Seashore as a result of construction activities. The only other actions associated with this alternative that could result in wetland impacts would be impacts from the continued use of ORVs throughout the Seashore.

Under alternative A, Seashore staff would continue to survey for various species as identified in the FONSI for the Interim Strategy. Seashore staff would use ATVs/UTVs and occasionally ORVs to conduct species surveys and to establish resource closures as required based on species behavior. There would be no impacts to estuarine wetlands, however, because species surveying and management would not typically occur in any areas where vegetated wetlands are located.

Under this alternative, visitors would be allowed to operate ORVs on all the ocean and inlet shoreline and on the existing soundside routes, 24 hours per day year-round, subject to temporary resource closures, seasonal ORV closures in front of the villages, and temporary ORV safety closures (see figure 2, chapter 2, alternative A and B maps). Anecdotal evidence from Seashore staff has demonstrated that some areas of estuarine wetlands at the Seashore have been denuded of vegetation from ORV use along the soundside shoreline. Studies at Cape Cod National Seashore also have noted the impacts from ORV use on vegetation (Broadhead and Godfrey 1977). Wetlands are also damaged when drivers attempt to avoid standing water on interior ORV routes at Cape Hatteras and, instead, drive over vegetation adjacent to these routes, as noted by Seashore staff. This use has the potential to result in wider roads and crushed or dead wetland vegetation. Long-term minor adverse impacts to estuarine vegetated wetlands at the Seashore would continue to occur under alternative A, as ORV drivers would continue driving over wetland vegetation along the soundside shoreline and adjacent to interior ORV routes.

Overall, under alternative A, there would be short-term negligible adverse impacts to marine intertidal wetlands due to continued ORV use in these areas and long-term minor adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the soundside and along interior ORV routes.

**Cumulative Impacts.** Other past, present, and future planned actions within and around Cape Hatteras National Seashore have the potential to impact wetlands. The dredging of Oregon Inlet has occurred in the past and would continue to be conducted on an annual basis by the Corps. Material from the dredging of Oregon Inlet is used primarily for replenishment of Pea Island NWR beaches. Because the dredged material is not deposited in vegetated wetlands, there should be no measurable impact to wetlands from this activity. However, the replacement of the Herbert C. Bonner Bridge is likely to adversely affect wetlands outside the NPS property because the preferred alternative for the bridge project would result in the filling and permanent loss of 3.1 acres of wetlands and open water habitat and would also involve temporary impacts to 12.5 acres of wetlands. To mitigate the permanent loss of 3.1 acres of wetlands, the Corps would restore, create, or enhance wetlands at agency-approved ratios at locations to be determined. Potential compensatory wetland mitigation would include on-site restoration and enhancement of in-kind wetlands as compensation for as much of the permanently affected area as possible; however, the limited availability of potential mitigation sites in the immediate vicinity of the project area would necessitate an exploration of additional options, which include off-site restoration, creation, and enhancement of wetlands (FHWA 2007).

The final bridge alignment could result in the closure of ramp 4 and the construction of a new ramp 3 and associated parking north of Oregon Inlet Campground. However, there would be sufficient upland area in which to construct ramp 3 and any associated parking. Therefore, there would be no impacts to wetlands

related to the construction of this new ramp and parking facilities. Because the bridge project would fill wetlands, it would have long-term impacts to wetlands, but mitigation would lessen these impacts. Other planned actions, such as improvements slated for NC-12 on Bodie Island, would not impact wetlands because there are no wetlands in the proposed project areas. The overall impacts of these past, current, and future actions on wetlands would be long-term minor to moderate adverse because construction would occur in wetland areas and would result in permanent wetland loss that would have a measurable effect on wetland indicators, but it would only impact 3.1 acres out of more than 1,000 acres of wetlands in the Bonner Bridge project area.

Local planning efforts and their policies toward development could also affect wetlands in the surrounding area. For example, the Hyde County Land Use Plan contains policy statements that indicate that the county will not adopt any local land use ordinances to regulate development in non-tidal wetlands. However, both Dare and Hyde counties recognize the importance of coastal wetlands, and these resources are protected as Areas of Environmental Concern (AECs) under the land use plans of both jurisdictions. In its 2003 Land Use Plan, Dare County recognizes the Buxton Woods forest as an example of one of the most unique maritime forests in North Carolina and establishes a special environmental zoning district (SED). SED-1 generally allows only single-family residential development, provides limits on vegetation clearing and impervious cover, and establishes a 50-foot buffer from wetlands. Almost all the wetlands in the study area are coastal, so they would also be afforded protection as an AEC under the North Carolina CAMA, which limits development in these areas to water-dependent uses only. Impacts to wetlands from potential new projects in Dare and Hyde counties, which would follow local planning policies, would be long-term adverse, but only negligible as these policies would ensure that development in coastal wetlands is minimized.

The effects of the actions described above—when combined with the short- and long-term negligible to minor adverse impacts to wetlands under alternative A—would result in long-term minor to moderate adverse cumulative impacts on wetlands in the area of analysis.

**Conclusion.** There would be short-term negligible adverse impacts to marine intertidal wetlands due to continued ORV use in these areas and long-term minor adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the soundside and along interior ORV routes.

Cumulative impacts to wetlands would be long-term minor to moderate adverse.

### **Impacts of Alternative B: No Action—Continuation of Management under Terms of the Consent Decree**

Under alternative B, there would be no new construction of ramps or roads and therefore no direct adverse impacts to Seashore wetlands as a result of construction activities. The only other actions associated with this alternative that could result in wetland impacts would be impacts from the continued use of ORVs throughout the Seashore.

Seashore staff would continue to conduct species surveying and management actions, as indicated in the FONSI and modified by the consent decree. The Seashore staff would use ATVs/UTVs and occasionally ORVs to conduct species surveys and establish resource closures as required based on species behavior. There would be no impacts to estuarine wetlands, however, because species surveying and management would not typically occur in any areas where vegetated wetlands are located. The level of impact from species surveying and management practices would be the same under the management that occurred before the modification of the consent decree on June 2, 2009.

Recreational use and other activities under alternative B would be similar to alternative A, except for seasonal restrictions on night driving and increased resource protection buffer distances. Although ORV traffic would be restricted in certain areas of the Seashore due to temporary resource closures and eliminated seasonally during the evening hours, there would still be ORV use along the soundside and interior, where damage to vegetated wetlands would continue during the day year-round and at nighttime from September 15 to April 30. Therefore, new restrictions on recreational ORV use under alternative B would not result in a measurable change in wetland impacts when compared to alternative A. Therefore, wetland impacts from recreational ORV use under alternative B would be long-term minor adverse.

Overall, under alternative B, there would be short-term negligible adverse impacts to marine intertidal wetlands due to continued ORV use in these areas and long-term minor adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the soundside and along interior ORV routes.

**Cumulative Impacts.** Past, present, and reasonably foreseeable future actions that have the potential for cumulative impacts under alternative B would be identical to those under alternative A. The effects of these actions—when combined with the short- and long-term minor adverse impacts to wetlands under alternative B—would result in long-term minor to moderate adverse impacts on wetlands in the area of analysis.

**Conclusion.** Overall, under alternative B, there would be short-term negligible adverse impacts to marine intertidal wetlands due to continued ORV use in these areas and long-term minor adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the soundside and along interior ORV routes.

Cumulative wetland impacts would be long-term minor to moderate adverse.

### **Impacts of Alternative C: Seasonal Management**

Unlike the no-action alternatives, alternative C would involve the construction and relocation of ORV access ramps (with some additional ramps being added), the construction or expansion of public parking areas, and the establishment of a new interdunal road. In addition to the construction activities proposed under alternative C, surveys for species presence or absence, associated management activities, and the recreational use of ORVs could potentially impact wetlands within the Seashore.

Access for recreational use and other activities under alternative C would be similar to alternatives A and B, except for the establishment of specific seasonal closures at the approximately 18 miles of SMAs under alternative C. Other areas outside of SMAs would be seasonally closed to ORV use under alternative C, according to table 7 in chapter 2. Under alternative C, the number of soundside access points would not change, but signs would be installed at the terminus of the soundside access points to reduce potential damage from vehicles to estuarine wetlands. Although alternative C includes additional measures for wetland protection on the soundside, long-term negligible adverse impacts to vegetated wetlands would occur due to the potential for ORVs driving over wetland vegetation along and adjacent to interior routes (including the expanded interdunal road network) and access roads that lead to soundside destinations.

Implementation of alternative C would involve the construction or relocation of six ORV access ramps, construction or expansion of seven public parking areas, and the establishment of a new interdunal road between ramps 45 and 49. All new access ramps and parking areas would be located exclusively in upland areas, thereby avoiding direct wetland impacts. Ramps would be surfaced with a semi-permeable clay/shell base, reducing runoff to any adjacent wetlands. New or expanded parking areas would be

designed and constructed with a semi-permeable clay/shell base, turf block, or some other porous material, using environmentally sensitive standards to minimize stormwater runoff. The new interdunal road proposed under alternative C would extend from the existing interdunal road at ramp 45 to ramp 49 (see figure 2, chapter 2 alternative C maps). Wetland maps indicate there is a sufficient upland area to extend the interdunal road, while avoiding wetland areas. The interdunal road would be primitive in nature (for example, not paved or otherwise hardened) and would not require surfacing. Wetland impacts resulting from the extension of the interdunal road would be avoided, although heavy use of the road could result in inadvertent wetland damage if vehicles were to leave the road surface for any reason, as wetlands are immediately adjacent to this area. Construction activities under alternative C would avoid wetland areas and use materials and management practices that would reduce surface runoff, resulting in indirect long-term negligible adverse impacts to wetlands.

Overall, under alternative C, there would be short-term negligible adverse impacts to marine intertidal wetlands due to continued ORV use in these areas and long-term negligible adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the soundside and along interior ORV routes. Impacts to soundside wetlands would remain at a negligible level due to the protection provided by the installation of signage under this alternative. Construction activities under alternative C would avoid wetland areas, resulting in indirect long-term negligible adverse impacts to wetlands.

**Cumulative Impacts.** Past, present, and reasonably foreseeable future actions that have the potential for cumulative impacts under alternative C would be identical to those under alternative A. The effects of these actions—when combined with the short- and long-term negligible adverse impacts to wetlands under alternative C—would result in long-term minor to moderate adverse impacts on wetlands in the area of analysis.

**Conclusion.** There would be short-term negligible adverse impacts to marine intertidal wetlands due to continued ORV use in these areas and long-term negligible adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the soundside and along interior ORV routes. Impacts to soundside wetlands would remain at a long-term negligible adverse level due to the protection provided by the installation of signage under this alternative. Construction activities under alternative C would avoid wetland areas and use materials and management practices that would reduce surface runoff, resulting in long-term negligible adverse impacts to wetlands.

Cumulative impacts under alternative C would be long-term minor to moderate adverse.

### **Impacts of Alternative D: Increased Predictability and Simplified Management**

Alternative D would involve the construction or relocation of four ORV access ramps. In addition to the ramp construction proposed under alternative D, species surveying and management activities and the recreational use of ORVs could potentially impact wetlands within the Seashore.

Vehicular access for recreational use and other activities under alternative D would be limited with the year-round “vehicle free” designation of all points, spits, and village beaches (see figure 2, chapter 2, alternative D maps). Soundside access would be managed the same as in alternative A, resulting in long-term negligible to minor adverse impacts to estuarine vegetated wetlands.

The proposed access ramps would be located exclusively in upland areas, thereby avoiding direct wetland impacts. Ramps would be constructed using environmentally sensitive standards to minimize stormwater runoff, as detailed in alternative C.

Overall, there would be short-term negligible adverse impacts to marine intertidal wetlands due to continued ORV use in these areas and long-term negligible to minor adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands along interior routes and on the soundside, which would not be protected with signage under this alternative. Construction activities under alternative D would avoid wetland areas, resulting in indirect long-term negligible adverse impacts to wetlands.

**Cumulative Impacts.** Past, present, and reasonably foreseeable future actions that have the potential for cumulative impacts under alternative D would be identical to those under alternative A. The effects of these actions—when combined with the short- and long-term negligible to minor adverse impacts to wetlands under alternative D—would result in long-term minor to moderate adverse impacts on wetlands in the area of analysis.

**Conclusion.** There would be short-term negligible adverse impacts to marine intertidal wetlands due to continued ORV use in these areas and long-term negligible to minor adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands along interior routes and on the soundside, which would not be protected with signage under this alternative. Construction activities under alternative D would avoid wetland areas and use materials and management practices that would reduce surface runoff, resulting in indirect long-term negligible adverse impacts to wetlands.

Cumulative impacts to wetlands under alternative D would be long-term minor to moderate adverse in the area of analysis.

### **Impacts of Alternative E: Variable Access and Maximum Management**

Implementation of alternative E would involve the installation or relocation of 7 ORV access ramps, construction or expansion of 14 public parking areas, and the establishment of 1 new interdunal road and 1 pedestrian trail. All new access ramps and parking areas would be located exclusively in upland areas, thereby avoiding direct impacts to wetlands. Ramps and parking areas would be constructed using environmentally sensitive standards to minimize stormwater runoff, as detailed in alternative C. The interdunal road under alternative E would extend from the existing interdunal road at ramp 45 to ramp 49. Wetland maps indicate that there is a sufficient upland area in which to extend the interdunal road, although there are adjacent wetland areas. Therefore, wetland impacts from the interdunal road extension would be avoided, although heavy use of the road could result in inadvertent wetland damage if vehicles were to leave the road surface for any reason, as Seashore staff indicates currently occurs. The proposed pedestrian trail and interdunal road extension would not involve any formal surfacing or removal of vegetation and would avoid all wetland features. Construction activities under alternative E would avoid wetland areas and use materials and management practices that would reduce surface runoff, resulting in long-term indirect negligible adverse impacts to wetlands.

To protect soundside wetland resources, several soundside access areas would be closed and protective signage would be installed at those areas that remain open to vehicular use. Closing some of the soundside access points would reduce the potential for damage to estuarine wetlands from vehicles and provide beneficial impacts to wetlands in these areas. Although wetlands on the soundside would be given more protection under this alternative, long-term negligible adverse impacts to wetlands would occur in areas where ORV access continues due to the potential for ORVs driving over wetland vegetation adjacent to the extended interdunal road network.

Overall, under alternative E, there would be short-term negligible adverse impacts to marine intertidal wetlands due to continued ORV use in these areas and long-term negligible adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the soundside and along interior

ORV routes. Impacts to soundside wetlands would remain at a negligible level due to the protection provided by signage and closure of access points under this alternative. Construction activities under alternative E would avoid wetland areas resulting in indirect long-term negligible adverse impacts to wetlands.

**Cumulative Impacts.** Past, present, and reasonably foreseeable future actions that have the potential for cumulative impacts under alternative E would be identical to those under alternative A. The effects of these actions—when combined with the short- and long-term negligible adverse impacts to wetlands under alternative E—would result in long-term minor to moderate adverse impacts on wetlands in the area of analysis.

**Conclusion.** There would be short-term negligible adverse impacts to marine intertidal wetlands due to continued ORV use in these areas and long-term negligible adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the soundside and along interior ORV routes. Impacts to soundside wetlands would remain at a long-term negligible adverse level due to the protection provided by signage and closure of access points under this alternative. Construction activities under alternative E would avoid wetland areas and use materials and management practices that would reduce surface runoff, resulting in indirect long-term negligible adverse impacts to wetlands.

Cumulative impacts under alternative E would be long-term minor to moderate adverse.

### **Impacts of Alternative F: NPS Preferred Alternative**

Implementation of alternative F would include the construction of 4 ORV access ramps and the relocation of 2 ramps, 2 new interdunal roads, pedestrian trails on Bodie and Ocracoke islands, and 12 new or expanded parking areas that would be surfaced, with a pervious material such as clay shell, with associated pedestrian access to the beach, that would add a total of approximately 135 parking spaces along the Seashore. All new access ramps and parking areas would be located exclusively in upland areas, thereby avoiding impacts to wetlands. Ramps and parking areas would be constructed using environmentally sensitive standards to minimize stormwater runoff, as detailed under alternative C. Under alternative F, new interdunal roads are proposed from ramp 45 to ramp 49 (with a new ramp at 47.5) and on Hatteras Inlet spit from the intersection of Pole and Spur roads southwest toward the inlet (stopping 100 meters from the inlet). Wetland maps indicate that there is a sufficient upland area in which to develop these interdunal roads. Therefore, direct wetland impacts from the interdunal road extensions would be avoided, although heavy use of the roads could result in inadvertent wetland damage if vehicles were to leave the road surface for any reason. The proposed pedestrian trail and interdunal road extensions would not require any formal surfacing or removal of vegetation and would avoid all wetland features.

To protect soundside wetlands and vegetation under alternative F, protective signage would be installed at all soundside access points to reduce the potential for resource damage from ORV use, thereby resulting in a beneficial impact. Although alternative F includes additional measures for wetland protection on the soundside, long-term negligible adverse impacts to wetlands would occur due to the potential for ORVs driving over wetland vegetation along and adjacent to interior routes (including the expanded interdunal road network) and access roads that lead to soundside destinations.

Overall, there would be short-term negligible adverse impacts to marine intertidal wetlands due to continued ORV use in these areas and long-term negligible adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the soundside and along interior ORV routes. Impacts to soundside wetlands would remain at a negligible level due to the protection provided by the

installation of signage. Construction activities under alternative F would avoid wetland areas, resulting in indirect long-term negligible adverse impacts to wetlands.

In accordance with NPS Director's Order 77-1: Wetlands Protection (and associated Procedural Manual 77-1), the preferred alternative, alternative F, was also evaluated for compliance with Executive Order 11990: Protection of Wetlands. Executive Order 11990 requires federal agencies to assess potential impacts to wetlands and avoid those impacts where possible. NPS activities that may adversely impact wetlands are subject to the provisions of Executive Order 11990 as implemented through Director's Order 77-1 and Procedural Manual 77-1. As stated in Procedural Manual 77-1, "the basic test for determining if a proposed action will have adverse impacts on wetlands is if the activity has the potential to degrade any of the natural and beneficial ecological, social/cultural, or other functions and values of wetlands...Such activities may require compliance due to direct impacts (e.g., placement of fill in a wetland) or due to indirect impacts (e.g., secondary or offsite impacts that reach into wetlands). Examples of activities with the potential to have adverse impacts on wetlands include drainage, water diversion, pumping, flooding, dredging, channelizing, filling, nutrient enrichment, diking, impounding, placing of structures or other facilities, livestock grazing, and other activities that degrade natural wetland processes, functions, or values" (Section 4.1.3).

Based on the above analysis, the continued use of ORVs and proposed construction activities under alternative F would not have new or additional measurable or perceptible effects on the size, integrity, or connectivity of wetlands. In addition to physical impacts to wetlands, new or additional impacts to the biological functions of wetlands, which provide habitat for invertebrates and birds foraging on the shoreline, were also considered. As described in the impact analysis under "Other Wildlife and Wildlife Habitat," impacts to these species from ORV use could be detectable (e.g., shorebirds foraging on the shoreline could be observed flushing due to disturbance by passing ORVs in those areas where ORVs would be allowed). These effects are considered minor because they would not be outside the range of natural variability. The preferred alternative would not create new or additional adverse impacts on wetland-dependent wildlife compared to existing ORV use. Alternative F would provide more area of shoreline that would not be open to ORV use than the existing and long-standing past management, which allowed ORV travel on almost all of the Seashore's oceanside beach, and also increased pedestrian impacts to foraging birds by carrying people to more distant locations. Therefore, it was determined that alternative F would not increase the degradation of wetlands functions and values as described in the NPS Procedural Manual 77-1, and in fact would decrease such impacts compared to existing ORV use. Therefore, a Statement of Findings for Wetlands was not prepared for this action.

**Cumulative Impacts.** Past, present, and reasonably foreseeable future actions that have the potential for cumulative impacts under alternative F would be identical to those described under alternative A. The effects of these actions—when combined with the short- and long-term negligible adverse impacts to wetlands under alternative F—would result in long-term minor to moderate adverse impacts on wetlands in the area of analysis.

**Conclusion.** There would be short-term negligible adverse impacts to marine intertidal wetlands due to continued ORV use in these areas and long-term negligible adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the soundside and along interior ORV routes. Impacts to soundside wetlands would remain at a long-term negligible adverse level due to the protection provided by the installation of signage. Construction activities under alternative F would avoid wetland areas, resulting in indirect long-term negligible adverse impacts to wetlands.

Cumulative impacts under alternative F would be long-term minor to moderate adverse.

**TABLE 50. SUMMARY OF IMPACTS TO WETLANDS UNDER THE ALTERNATIVES**

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
Under all alternatives, there would be short-term negligible adverse impacts to marine intertidal wetlands due to continued ORV use in these areas.					
Under alternative A, there would be long-term minor adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the soundside and along interior ORV routes.	Under alternative B, there would be long-term minor adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the soundside and along interior ORV routes.	Under alternative C, there would be long-term negligible adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the soundside and along interior ORV routes. Impacts to soundside wetlands would remain at a negligible level due to the protection provided by the installation of signage.	Under alternative D, there would be long-term negligible to minor adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the soundside, which would not be protected with signage. Impacts to vegetated wetlands along interior ORV routes would continue.	Under alternative E, there would be long-term negligible adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the soundside and along interior ORV routes. Impacts to soundside wetlands would remain at a negligible level due to the protection provided by signage and closures of soundside access points.	Under alternative F, there would be long-term negligible adverse impacts to wetlands due to direct damage from ORV use in and around vegetated wetlands on the soundside and along interior ORV routes. Impacts to soundside wetlands would remain at a negligible level due to the protection provided by the installation of signage.
There would be no construction (or related impacts) under the no-action alternatives.		Construction activities would avoid wetland areas, resulting in indirect long-term negligible adverse impacts to wetlands.			

**FLOODPLAINS**

**Assumptions**

Assumptions made in assessing potential impacts to floodplains include the following:

- FEMA Flood Insurance Rate Maps indicate almost the entire Seashore is within the 100-year floodplain.
- The floodplains in the project area do not serve the same function (i.e., as a natural moderator of floods) as floodplains in non-coastal areas because water levels in the project area are not dependent on floodplain storage capacity. Rather the project area is subject to coastal flooding caused by both hurricanes and other storm systems that can raise water levels substantially via storm surge.
- Recreational ORV use in the project area would not result in impacts to floodplain functions or values. The only impacts to floodplains from the implementation of the alternatives would be those impacts associated with proposed construction activities.

**Impact Thresholds**

A summary of floodplains impacts under all alternatives is provided in table 51 at the end of this section. The following thresholds for evaluating impacts to floodplains were defined.

- Negligible:* Impacts would result in a change to floodplain functions and values, but the change would be so slight that it would not be of any measurable or perceptible consequence.
- Minor:* Impacts would result in a detectable change to floodplain functions and values, but the change would be expected to be small, of little consequence, and localized. There would be no appreciable increased risk to life or property. Mitigation measures, if needed to offset adverse effects, would be simple and successful.
- Moderate:* Impacts would result in a change to floodplain functions and values that would be readily detectable and relatively localized. Location of operations in floodplains could increase risk to life or property. Mitigation measures, if needed to offset adverse effects, could be extensive, but would likely be successful.
- Major:* Impacts would result in a change to floodplain functions and values that would have substantial consequences on a regional scale. Location of operations would increase risk to life or property. Extensive mitigation measures would be needed to offset any adverse effects, and their success would not be guaranteed.
- Duration:* Short-term: the floodplain recovers in less than one year from any action taken.
- Long-term: the floodplain takes longer than one year to recover or the effect is almost permanent.

## Study Area

The study area for assessment of the various alternatives is the Seashore. The study area for the cumulative impacts analysis is the Seashore plus the adjacent lands outside of the Seashore boundaries on Bodie, Hatteras, and Ocracoke islands.

### **Impacts of Alternative A: No Action—Continuation of Management under the Interim Protected Species Management Strategy**

Under alternative A, no construction is proposed. The management actions associated with alternative A (including the use of ORVs and ATVs/UTVs for recreation and species management activities) would not have a measurable effect on floodplains because driving on beaches, interior ORV routes, or along soundside ORV access routes would not impact the natural function of the floodplain.

**Cumulative Impacts.** Because there would be no impacts on floodplain functions or values under the no-action alternative, no cumulative impacts would occur.

**Conclusion.** Implementation of alternative A would result in no impacts to the functions or values of the currently existing floodplains found within the study area.

Because there would be no impacts on floodplain functions or values under the no-action alternative, no cumulative impacts would occur.

## **Impacts of Alternative B: No Action—Continuation of Management under Terms of the Consent Decree**

**Analysis.** No construction is proposed under alternative B. No management actions associated with alternative B (including the use of ORVs and ATVs/UTVs for recreation or species management activities) would have a measurable effect on floodplains as driving on beaches, interior ORV routes, or along soundside ORV access routes would not impact the natural function of the floodplain. Management practices in use prior to the modification of the consent decree on June 2, 2009, would not result in any impacts to floodplains.

**Cumulative Impacts.** Because there would be no impacts on floodplain functions or values under alternative B, no cumulative impacts would occur.

**Conclusion.** Implementation of alternative B would result in no adverse, beneficial, or cumulative impacts on the functions or values of the currently existing floodplains found within the study area. Because there would be no impacts on floodplain functions or values under the no-action alternative, no cumulative impacts would occur.

## **Impacts of Alternative C: Seasonal Management**

The use of vehicles for species management and recreational access would not result in any impacts to floodplain functions or values, as described under the no-action alternatives. However, construction activities proposed under alternative C have the potential to impact the floodplain, as discussed below.

Alternative C would involve the construction or relocation of six ORV access ramps, construction or expansion of seven public parking areas, and the establishment of one new interdunal road, as shown on figure 2 in chapter 2. Because all of the area between access roads (interdunal or NC-12) and the shoreline is in the 100-year floodplain, no options for constructing the proposed facilities outside of the regulatory floodplain exist. Ramps would be surfaced with a natural semi-permeable clay/shell base, reducing stormwater runoff and limiting the potential for impacts to the floodplain's function. New or expanded parking areas would be designed and constructed with a semi-permeable clay/shell base, turf block, or some other porous material, using environmentally sensitive standards to minimize stormwater runoff. All of the parking areas would be located within the 100-year floodplain, with none of the new or expanded lots located in areas seaward of the primary dune line. New or expanded parking areas would be located outside of coastal high hazard areas subject to flash flooding, when possible. Although Director's Order 77 allows the construction of day-use parking facilities within the 100-year floodplain in high hazard areas, signs informing visitors of flood risk and suggested actions in the event of flooding must be posted, and are included as part of alternative C, if it is not possible to locate all of the proposed parking areas outside of high hazard areas. The interdunal road proposed under alternative C would extend from the existing interdunal road at ramp 45 to ramp 49. The road, constructed at grade, would not alter topography or require a finished surface, limiting the potential for impacts to floodplain function. The construction or expansion of the seven parking areas would result in the placement of hardened, pervious surface in the 100-year floodplain and would have a limited effect on the ability of the floodplain to convey floodwaters from storm surge. Although impacts would result in a detectable change in floodplain functions and values, the change would be of little consequence and localized in nature. Therefore, under alternative C, there would be long-term minor adverse impacts to floodplains due to the construction or expansion of seven parking areas in the floodplain.

**Cumulative Impacts.** Other past, present, and future planned actions within and around the Seashore have the potential to impact floodplains. The dredging of Oregon Inlet has occurred in the past and would continue to occur on an annual basis. Material from the dredging of Oregon Inlet is used primarily for the

replenishment of Pea Island NWR beaches. The deposition of this material has the potential to impact the function of the floodplain if substantial changes to topography resulted in the diversion of floodwaters into developed or inhabited areas. However, due to the dynamic coastal processes that continually reshape the area of deposition and the lack of development in the vicinity, impacts to the floodplain from dredging activities would be negligible at most. The replacement of the Herbert C. Bonner Bridge is likely to affect floodplains because all of the replacement bridge corridor alternatives—as well as the existing Bonner Bridge and NC 12—are within the floodplain. However, the replacement bridge should not have measurable impacts on floodplain values because the piles of the bridge substructure would not create backwater or adverse hydraulic conditions, and floodplain functions would not be expected to be impacted. All alternatives for the replacement of the Herbert C. Bonner Bridge conform to applicable state and local floodplain protection standards because they would not affect the storm surge elevation. However, the location of structures and impervious surfaces in the floodplain could result in localized flooding during heavy rain events. Other planned actions, such as improvements slated for NC-12 on Bodie Island would contribute limited adverse impacts to floodplains because they would result in additional development or hardened surfaces in the floodplain that could impact the overall floodplain functions. The overall impacts of these past, current, and future actions on floodplains would be long-term minor to moderate adverse due to the development that would occur in the floodplain and the resulting potential to impact floodplain functions.

Local planning efforts and their policies toward development could also affect floodplains in the surrounding area. Both Dare and Hyde counties recognize the risks associated with floodplain development and support the administration and enforcement of all applicable floodplain management regulations and the National Flood Insurance Program. Almost all of the shoreline in the study area is in a high hazard flood area and would also be protected as an AEC under the CAMA, which limits development in these areas. Impacts to floodplains from local planning policies would be beneficial because the local policies, along with existing federal regulations, would limit development in these areas. However, some level of development would be expected to occur in these areas in the future, so these floodplains would continue to be impacted.

The effects of the actions described above—when combined with the long-term minor adverse impacts to floodplains under alternative C—would result in long-term minor to moderate adverse impacts on floodplains in the area of analysis.

**Conclusion.** There would be long-term minor adverse impacts to floodplains resulting from the implementation of alternative C due to the construction or expansion of seven parking areas within the 100-year floodplain. Installation of ORV access ramps would not impact floodplains because they would be composed of pervious materials. Interdunal roads would not be surfaced and would therefore not result in floodplain impacts.

Past, present, and reasonable foreseeable future actions—when combined with the impacts of implementing alternative C—would result in long-term minor to moderate adverse cumulative impacts to floodplains in the area of analysis.

### **Impacts of Alternative D: Increased Predictability and Simplified Management**

The use of vehicles for species and management and recreational access would not result in any impacts to floodplain functions or values, as described under the no-action alternatives. However, construction activities proposed under alternative D have the potential to impact the floodplain, as discussed below.

Alternative D would require the least amount of construction of the action alternatives and would involve the construction or relocation of four ORV access ramps. Because nearly the entire Seashore is within the

floodplain, there would be no options for constructing the proposed facilities outside of the regulatory floodplain. The four ramps proposed under alternative D would be surfaced with a natural semi-permeable clay/shell base, thereby reducing stormwater runoff and limiting the potential for impacts to floodplain function. There would be no additions or alterations to interdunal roads or parking areas under alternative D. Therefore, under alternative D, there would be long-term negligible adverse impacts to floodplains due to the location of four ORV access ramps in the 100-year floodplain.

**Cumulative Impacts.** Past, present, and reasonably foreseeable future actions that have the potential for cumulative impacts under alternative D would be identical to those under alternative C. The effects of these actions—when combined with the long-term negligible adverse impacts to floodplains under alternative D—would result in long-term minor to moderate adverse impacts to floodplain functions and values in the area of analysis.

**Conclusion.** There would be long-term negligible adverse impacts to floodplains resulting from the implementation of alternative D due to the installation or relocation of four ORV access ramps.

Past, present, and reasonable foreseeable future actions—when combined with the impacts of implementing alternative D—would result in long-term minor to moderate adverse cumulative impacts to floodplains in the area of analysis.

### **Impacts of Alternative E: Variable Access and Maximum Management**

The use of vehicles for species management and recreational access would not result in any impacts to floodplain functions or values, as described under the no-action alternatives. However, construction activities proposed under alternative E have the potential to impact the floodplain, as discussed below.

Implementation of alternative E would involve the construction or relocation of 7 ORV access ramps, construction or expansion of 14 public parking areas, and the establishment of 1 new interdunal road and 1 pedestrian trail. As discussed under alternative C, the establishment of ramps and extension of interdunal roads would not result in floodplain impacts because no impervious surfaces or above-grade structures would be constructed and floodplain functions would not be altered. The development of a pedestrian trail near Oregon Inlet under alternative E also would not result in floodplain impacts because the trail would be primitive in nature and would not be paved or surfaced. Because all of the area between access roads (interdunal or NC-12) and the shoreline is in the 100-year floodplain, no options for constructing the proposed facilities outside of the regulatory floodplain exist. Ramps and parking areas would be designed and constructed using environmentally sensitive standards and materials to minimize stormwater runoff, as detailed in alternative C. All of the parking areas would be located within the 100-year floodplain, with none of the new or expanded lots located in areas seaward of the primary dune line. New or expanded parking areas would be located outside of coastal high hazard areas subject to flash flooding when possible. Although Director's Order 77 allows the construction of day-use parking facilities within the 100-year floodplain in high hazard areas, signs informing visitors of flood risk and suggested actions in the event of flooding must be posted, and are included as part of alternative E, if it is not possible to locate all of the proposed parking areas outside of high hazard areas. The construction or expansion of the seven parking areas would result in the placement of hardened, pervious surface in the 100-year floodplain and would have a limited effect on the ability of the floodplain to convey floodwaters from storm surge. Although impacts would result in a detectable change in floodplain functions and values, the change would be of little consequence and localized in nature. Therefore, under alternative E, there would be long-term minor adverse impacts to floodplains due to the construction or expansion of 14 parking areas in the floodplain.

**Cumulative Impacts.** Under alternative E, the same past, present, and planned future activities within the Seashore that have the potential to affect floodplains would occur, and impacts would be the same as described under alternatives C and D. The effects of these actions—when combined with the long-term minor adverse impacts to floodplains under alternative E—would result in long-term minor to moderate adverse impacts to floodplain functions and values in the area of analysis.

**Conclusion.** There would be long-term minor adverse impacts to floodplains resulting from the implementation of alternative E due to the construction or expansion of 14 parking areas throughout the Seashore.

Past, present, and reasonable foreseeable future actions—when combined with the impacts of implementing alternative E—would result in long-term minor to moderate adverse cumulative impacts to floodplains in the area of analysis.

### **Impacts of Alternative F: NPS Preferred Alternative**

The use of vehicles for species and management and recreational access would not result in any impacts to floodplain functions or values, as described under the no-action alternatives. However, construction activities proposed under alternative F have the potential to impact the floodplain, as discussed below.

Implementation of alternative F would include the construction of 4 ORV access ramps and the relocation of 2 ramps, 2 new interdunal roads, pedestrian trails on Bodie and Ocracoke islands, and 12 new or expanded parking areas that would be surfaced, with a pervious material such as clay shell, with associated pedestrian access to the beach, that would add a total of approximately 135 parking spaces along the Seashore. As discussed under alternative C, the establishment of ramps and interdunal roads would not result in floodplain impacts because no impervious surfaces or above-grade structures would be constructed, and floodplain functions would not be altered. The development of pedestrian trails under alternative F would also not result in floodplain impacts because the trails would be primitive in nature and would not be paved or surfaced in any way.

Because all of the area between access roads (interdunal or NC-12) and the shoreline is in the 100-year floodplain, no options for constructing the proposed facilities outside of the regulatory floodplain exist. Ramps and parking areas would be designed and constructed using environmentally sensitive standards and materials to minimize stormwater runoff, as detailed in alternative C. All of the parking areas would be located within the 100-year floodplain, with none of the new or expanded lots located in areas seaward of the primary dune line. New or expanded parking areas would be located outside of coastal high hazard areas subject to flash flooding when possible. Although Director's Order 77 allows the construction of day-use parking facilities within the 100-year floodplain in high hazard areas, signs informing visitors of flood risk and suggested actions in the event of flooding must be posted, and are included as part of alternative F, if it is not possible to locate all of the proposed parking areas outside of high hazard areas. The construction or expansion of 12 proposed parking areas would result in the placement of hardened, pervious surface in the 100-year floodplain and would have a limited effect on the ability of the floodplain to convey floodwaters from storm surge. The two on-sand parking areas accessible by 4-wheel drive vehicles at the terminus of the new interdunal routes would not require a hardened surface because vehicles would travel over sand to reach them. Although impacts would result in a detectable change in floodplain functions and values, the change would be of little consequence and localized in nature. Therefore, under alternative F, there would be long-term minor adverse impacts to floodplains due to the construction or expansion of 12 parking areas with permeable surfaces in the floodplain. Per Director's Order 77, a Statement of Findings for floodplains has been prepared for this alternative and is attached in appendix B of this document.

**Cumulative Impacts.** Under alternative F, the same past, present, and planned future activities within the Seashore that have the potential to affect floodplains would occur, and impacts would be the same as described under alternatives C, D, and E. The effects of these actions—when combined with the long-term minor adverse impacts to floodplains under alternative F—would result in long-term minor to moderate adverse impacts to floodplain functions and values in the area of analysis.

**Conclusion.** There would be long-term minor adverse impacts to floodplains resulting from the implementation of alternative F due to the construction or expansion of 12 parking areas in the 100-year floodplain.

Past, present, and reasonable foreseeable future actions—when combined with the impacts of implementing alternative F—would result in long-term minor to moderate adverse cumulative impacts to floodplains in the area of analysis.

**TABLE 51. SUMMARY OF IMPACTS TO FLOODPLAINS UNDER THE ALTERNATIVES**

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
There would be no construction under alternative A. As a result, there would be no impacts to the functions or values of floodplains.	There would be no construction under alternative B. As a result, there would be no impacts to the functions or values of floodplains.	Under alternative C, there would be long-term minor adverse impacts to floodplains due to the construction or expansion of seven parking areas in the floodplain.	Under alternative D there would be long-term negligible adverse impacts to floodplains due to the location of four ORV access ramps in the 100-year floodplain.	Under alternative E, there would be long-term minor adverse impacts to floodplains due to the construction or expansion of 14 parking areas in the floodplain.	Under alternative F, there would be long-term minor adverse impacts to floodplains due to the construction or expansion of 12 parking areas with permeable surfaces in the floodplain.

## FEDERALLY LISTED THREATENED OR ENDANGERED SPECIES

### GUIDING REGULATIONS AND POLICIES

The ESA (16 USC 1531 et seq.) mandates that all federal agencies consider the potential effects of their actions on species listed as threatened or endangered. If the NPS determines that an action may affect a federally listed species, consultation with the USFWS is required to ensure that the action would not jeopardize the species' continued existence or result in the destruction or adverse modification of critical habitat. *NPS Management Policies 2006* state that the NPS will survey for, protect, and strive to recover all species native to NPS units that are listed under the ESA, and proactively conserve listed species and prevent detrimental effects on these species (NPS 2006c, sec. 4.4.2.3). *NPS Management Policies 2006* also state that “[the NPS will] manage state and locally listed species in a manner similar to its treatment of federally listed species to the greatest extent possible” (NPS 2006c, sec. 4.4.2.3).

### ASSUMPTIONS, METHODOLOGY, AND IMPACT THRESHOLDS

The following information was used to assess impacts on all listed species from ORV management actions:

1. Species found in areas likely to be affected by actions described in the alternatives.
2. Habitat loss or alteration caused by the alternatives.

3. Displacement and disturbance potential of the actions and the species' potential to be affected by the activities.

According to the ESA, the term “take” means to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct.

Specific methodologies and assumptions pertaining to the piping plover, sea turtles, or seabeach amaranth are described under the relevant descriptions in the following text.

When examining the impacts of artificial light on threatened and endangered species (primarily sea turtles), the lighting zones developed for Cape Hatteras National Seashore by the NPS Night Skies Team were considered. In these zones, special consideration is given to areas with sensitive wildlife, and alternate guidance is provided to enhance the protection of nocturnal habitat. These special lighting zones represent the conditions that should be present at the Seashore, not necessarily actual current conditions, and create a buffer when two varying zones abut each other.

Although the action alternatives involve the construction of ramps, parking areas, and interdunal roads, construction activities would occur outside of the bird breeding season, during daylight hours, and outside of any protected species breeding or foraging habitat. In the unlikely event that threatened and endangered species are found in a construction area, the area would be under a resource closure and no construction would occur. Therefore, impacts from construction were assumed to be negligible.

The following assumption was made regarding the analysis for all alternatives:

An indirect impact from recreation use is the attraction of mammalian and avian predators to trash associated with recreation use (USFWS 1996a, 2009a). Predation continues to be a major factor affecting the reproductive success of piping plovers (Elliot-Smith and Haig 2004). The Seashore would enforce proper trash disposal and anti-wildlife feeding regulations to reduce the attraction of predators to the area under all alternatives. Nevertheless, as demonstrated by the Seashore's annual piping plover reports, predation continues to be a threat to piping plover success at the Seashore (see “Chapter 3: Affected Environment”). Recreational use that brings humans into areas where plovers reside would continue to have indirect impacts by attracting predators, resulting in long-term moderate impacts under all alternatives as impacts could be detectable and outside the range of natural variability, but would not result in large declines in population as the Seashore takes steps to protect listed species from predation.

The ESA defines the terminology used to assess impacts to the piping plover, sea turtles, and seabeach amaranth as follows.

- No effect:* When a proposed action would not affect a listed species or designated critical habitat.
- May affect / not likely to adversely affect:* When effects on listed species are expected to be discountable, insignificant, or completely beneficial. Beneficial effects are contemporaneous positive effects without any adverse effects to the species. Insignificant effects relate to the size of the impact and should never reach the scale where “take” occurs. Discountable effects are those extremely unlikely to occur. Based on best judgment, a person would not (1) be able to meaningfully measure, detect, or evaluate insignificant effects; or (2) expect discountable effects to occur.

*May affect / likely to adversely affect:* When any adverse effect to listed species may occur as a direct or indirect result of the proposed action or its interrelated or interdependent actions, and the effect is not discountable, insignificant, or beneficial. If the overall effect of the proposed action is beneficial to the listed species, but is also likely to cause some adverse effects, the proposed action “is likely to adversely affect” the listed species. If incidental take is anticipated to occur as a result of the proposed action, then it “is likely to adversely affect” the species. Incidental take is the take of a listed species that results from, but is not the purpose of, carrying out an otherwise lawful activity.

*Is likely to jeopardize species / adversely modify critical habitat:* The appropriate conclusion when the NPS or the USFWS identifies an adverse effect that could jeopardize the continued existence of a species or destroy or adversely modify critical habitat of a species within or outside Seashore boundaries.

The EIS will serve as the biological assessment in compliance with Section 7 consultation requirements and analyzes impacts using the above terminology. Each alternative includes an ESA summary after the conclusion section to facilitate this compliance. To provide the public with additional information on the intensity of impacts, the NEPA thresholds for each species were defined and used throughout the analysis.

## Study Area

The study area for assessment of the various species is described separately for each listed species.

## PIPING PLOVER

### Species-Specific Methodology and Assumptions

Potential impacts on the federally threatened piping plover populations and habitat were evaluated based on available data on the species’ past and present occurrence at Cape Hatteras National Seashore, scientific literature on the species, life history, scientific studies on the impacts of human disturbance on piping plovers, as well as documentation of the species’ association with humans, pets, predators, and ORVs. Information on habitat and other existing data were acquired from staff at Cape Hatteras National Seashore, the USFWS, and available literature.

### Piping Plover Impact Thresholds

A summary of piping plover impacts under all alternatives is provided in table 52 at the end of this section.

The following thresholds for evaluating impacts to piping plovers were defined.

*Negligible:* There would be no observable or measurable impacts to piping plovers, their habitats, or the natural processes sustaining them. Impacts would be well within natural fluctuations.

- Minor Adverse:* Impacts on piping plovers would be detectable, but would not be outside the natural range of variability. Occasional responses by some individuals to disturbance could be expected, and may result in minimal interference to feeding, reproduction, resting, or other factors affecting population levels, but would not be expected to result in changes to local population numbers, population structure, and other demographic factors. Some impacts might occur during critical reproduction periods for piping plover, but would not result in injury or mortality. Sufficient habitat in the Seashore would remain functional to maintain a sustainable population in the Seashore.
- Minor Beneficial:* Impacts on piping plover, their habitats, or the natural processes sustaining them would be detectable, but would not be outside the natural range of variability. Improvements to key characteristics of habitat and/or protection to key life history stages in the Seashore would sustain or slightly improve existing population levels, population structure, or other factors and maintain a sustainable population in the Seashore.
- Moderate Adverse:* Impacts on piping plover, their habitats, or the natural processes sustaining them would be detectable and could be outside the natural range of variability. Frequent responses by some individuals to disturbance could be expected, with some negative impacts to feeding, reproduction, resting, or other factors affecting local population levels. Small changes to local population numbers, population structure, and other demographic factors may occur. Some impacts might occur during critical periods of reproduction or in key habitats in the Seashore and result in harassment, injury, or mortality to one or more individuals. However, sufficient population numbers and habitat in the Seashore would remain functional to maintain a sustainable population in the Seashore.
- Moderate Beneficial:* Impacts on piping plover, their habitats, or the natural processes sustaining them would be detectable and could be outside the natural range of variability. Changes to key characteristics of habitat in the Seashore and/or protection to key life history stages would minimize or prevent harassment or injury to individuals and improve the sustainability of the species in the Seashore.
- Major Adverse:* Impacts on piping plover, their habitats, or the natural processes sustaining them would be detectable and would be expected to be outside the natural range of variability. Frequent responses by some individuals to disturbance would be expected, with negative impacts to feeding, reproduction, or other factors resulting in a decrease in Seashore population levels or a failure to restore levels that are needed to maintain a sustainable population in the Seashore. Impacts would occur during critical periods of reproduction or in key habitats in the Seashore and result in direct mortality or loss of habitat. Local population numbers, population structure, and other demographic factors might experience large declines.
- Major Beneficial:* Impacts on piping plover, their habitats in the Seashore, or the natural processes sustaining them during key life history stages would be detectable and would be expected to be outside the natural range of variability. Changes to key characteristics of habitat in the Seashore and/or protection to key life history stages would substantially lessen mortality or loss of habitat and would result in notable increases in Seashore population levels.

*Duration:* Short-term effects would be one to two breeding seasons for piping plover.

Long-term effects would be anything beyond two breeding seasons for piping plover.

## Study Area

The study area for assessment of the various alternatives is the Seashore. The study area for the cumulative impacts analysis is the Seashore and the region, including the Carolina area included in the recovery plan for the piping plover (USFWS 1996a).

## Impacts of Alternative A: No Action—Continuation of Management under the Interim Protected Species Management Strategy

### Resources Management Activities

Under alternative A, piping plover surveys would occur at the spits, Cape Point, and South Beach once a week from March 15 to March 31, and increase to three times a week from April 1 to June 15. When nests are located, surveying would further increase to once daily.

*Establishment of Prenesting Closures.* Prenesting closure areas would be established in areas used by piping plover sometime during the past three breeding seasons (defined as “recent breeding” habitat) with symbolic fencing to minimize human disturbance. An annual habitat assessment would be conducted in February or March. Based on this assessment, new habitat and suitable portions of recent breeding habitat, such as some shoreline foraging areas and nesting habitat, would be closed to the public with symbolic fencing by April 1 each year. This annual habitat assessment would include Bodie Island Spit, Cape Point, South Beach, Hatteras Inlet Spit, North Ocracoke Spit, and South Point. Alternative A would provide protection at recent breeding sites, closing portions of them to access by April 1, but would not protect habitat not used prior to the last three years. This could cause adverse impacts, because any piping plovers attempting to use these unprotected areas in the early spring (prior to April 1) may abandon their attempts due to human disturbance (e.g., vehicles, pedestrians, kites) prior to being detected by weekly surveys. Under alternative A, piping plovers would likely benefit from surveying and resultant closures in the prenesting phase, however since closures are not established until April 1, individuals nesting prior to that would not benefit from these closures and would receive protection only if found during surveying (see below). As early nesting piping plover would not be afforded protection from prenesting closures, there would be long-term minor to moderate adverse impacts, since there may be impacts during critical periods of reproduction. Once the prenesting closures are in place, long-term moderate beneficial impacts would occur for piping plover at the Seashore.

*Surveying and Monitoring.* Beginning March 15 staff would survey recent piping plover breeding areas once a week and beginning April 1, staff would survey recent piping plover breeding areas three times per week. A range of observations, as required by the USFWS Amended Biological Opinion (USFWS 2007a, outlined in table 1 of the FONSI), would occur for each bird species by qualified staff across all life stages. Staff would observe species activities and potentially close areas, outside of defined prenesting closures, being used by piping plovers or other protected bird species. Closures would be removed if no bird activity is seen by July 15 or when the area has been abandoned for a 2-week period, whichever comes later. When piping plover nests are found in existing or newly established closure areas, Seashore staff would collect a variety of data including number of observations of plovers performing territorial defense or courtship outside symbolic fencing; number of observations of plovers making nest scrapes outside the symbolic fencing; and the number of vehicles, pedestrians, or pets within the symbolic fencing

and/or in which tracks are observed crossing into posted habitat. Although surveying would bring people and/or essential vehicles into direct short-term contact with piping plovers and their habitat, and these activities themselves are a known risk factor, implementing precautions to minimize impacts, for example, using scopes to watch the birds from a distance and remaining outside closures to the extent possible, and the protection that results from surveying may result in long-term minor to moderate beneficial impacts.

*Buffer/Closure Establishment.* Under alternative A, outside of prenesting closures, if courtships or copulations are observed for two consecutive survey days, a buffer would be established, or expanded, to ensure a 164-foot buffer for the observed birds. When nesting occurs, a 164-foot buffer/closure would be established around piping plover nests outside existing closures. These closures would be expanded, if necessary to prevent disturbance, using flexible increments dependent on observed bird behavior. When resource closures are created around nests, the ORV corridor would be adjusted whenever possible to allow for vehicle passage, and the width of this corridor would be reduced if necessary. Closures could also be expanded if adults are observed foraging outside of a closure on two consecutive surveys, and in this case, the buffer would be expanded to include the foraging site. For unfledged chicks, alternative A would establish a minimum 600-foot buffer on either side of the brood based on observation of bird behavior and terrain conditions at the site. Chicks would be observed continuously during daylight hours during the first week. Based on observed behavior, the buffer area may require expansion up to 3,000 feet if chicks are highly mobile. Based on observed behavior (i.e., mobility of the brood) and the capability to continually observe mobility and behavior, the buffer zone could be reduced after the first week to no less than 300 feet, but might require expansion up to 3,000 feet if chicks are subsequently observed to exhibit high mobility. After the first week, if the closure is reduced or remains the same, continuous observation would continue and if the closure is enlarged, observations would be reduced to once daily. These buffers would move with the chicks and provide them with more protection than stationary buffers. Bypass routes would be closed at night if the buffer zone is less than 600 feet.

When closures are created around broods, the ORV corridor would be adjusted whenever possible to allow vehicle passage. For areas in which the buffer zone eliminates the ORV corridor, alternate ORV routes would be identified if available. If there are no alternate ORV routes, a bypass would be established if possible. Under alternative A, beaches would be closed to recreational access down to the waterline, if necessary, to allow chicks access to foraging areas, thereby providing chicks with maximum protection during this sensitive life stage. Under this type of management, staff would observe piping plover chicks from a distance to minimize disturbing the birds and allow the birds to forage or rest as they would under undisturbed conditions.

Alternative A provides for protection of piping plover nests through the use of buffer distances recommended in the Piping Plover Recovery Plan (USFWS 1996a). Further, additional information would be collected during this life stage from daily observations via use of optical equipment outside the symbolic fencing and from close approaches to nests once per week to observe and record data. Staff observing bird location and behavior would have the flexibility to adjust closure buffers, as some individual piping plovers might require larger buffers than others (USFWS 1996a). Adverse impacts could result to piping plovers if adjustments to the buffer are not made in a timely manner or if nests are missed by observers. Except for the once per week nest examination, the buffers under alternative A would be expected to have long-term minor beneficial effects on the species as Seashore personnel and recreationists who respect resource closures would be kept a safe distance (at least 150 feet) from incubating adults and their nests.

Piping plovers would likely experience minor long-term benefits from the size of resource closures and observation intensity adjustments in response to chick behavior, which would be especially responsive to highly mobile broods. However, basing buffer size on chick behavior and adjusting these buffers as

necessary may also result in long-term moderate adverse impacts as frequent adjustment of the buffers may result in additional disturbance to piping plover, and buffers that are not adjusted in a timely manner could result in less than optimal protection for the species.

*Management of Wintering/Nonbreeding Populations.* As provided in the USFWS Amended Biological Opinion (USFWS 2007a), the NPS would monitor the presence, abundance, and behavior of migrating and wintering piping plovers from August 1 to March 31 of each year. During surveys, specific observations would be made regarding vehicle, pedestrian, and pet tracks in posted habitat; signs of predators, including species; specific management measures in place at the time of the observation; observed behaviors; and reactions to disturbance by pedestrians, pets, or vehicles. Data collected would result in minor to moderate beneficial impacts to plovers by providing Seashore managers with information on the types and locations of habitats used, seasonality of plover use of the Seashore, tidal influence on habitat use, and potential threats the habitat may contain. Surveying would increase knowledge on how and when piping plovers use the Seashore.

Under alternative A, suitable interior habitats at spits and at Cape Point would be closed year-round to all recreational users and would result in long-term minor beneficial impacts as this would prevent degradation or disturbance of habitat during key life stages of the species. Suitable habitats could include ephemeral ponds and moist flats at Cape Point, Hatteras Inlet Spit, North Ocracoke Spit, South Point (Ocracoke), and Bodie Island Spit. Actual locations of suitable foraging and resting habitat would change periodically due to natural processes such as tides and storms.

*Education/Public Outreach.* Under alternative A, the public would continue to receive information at the visitor centers about piping plovers and their ecology and the measures the Seashore is taking to protect the species. The public would also continue to be notified about closures that would limit ORV or pedestrian traffic, as well as when these closures reopen. Such public outreach is beneficial to the species as it educates the public to the specific needs of the species and alerts the public ahead of time to areas where they cannot go due to potential impacts to the species. Therefore, public outreach as part of species management would have long-term minor beneficial impacts.

*Overall Impacts of Resources Management Activities.* Overall, impacts to piping plover from resources management activities (primarily resulting from the effects of species surveying and field activities), would be long-term minor to moderate adverse. Although the management of the species would provide a certain level of benefit, the manner in which buffers would be established, along with the need to adjust buffers frequently would have an adverse impact on the species.

## **ORV and Other Recreational Use**

*ORV and Pedestrian Access.* Under this alternative, visitors would be allowed to operate ORVs on all the ocean and inlet shoreline and on the existing soundside routes, 24 hours per day year-round, subject to temporary resource closures, seasonal ORV closures in front of the villages, and temporary ORV safety closures (see figure 2, chapter 2, alternative A and B maps). This would have potential adverse impacts, since it would not guarantee that all piping plover foraging and nesting habitat would be protected as one contiguous unit. Alternative A would designate an approximately 100-foot-wide ORV corridor above the mean high tide line in breeding areas used within the past three years and would delineate the corridor with posts placed up to 100 feet above the high tide line. In areas of reduced corridor width (i.e., less than 100 feet), traffic signs would be posted indicating a 10 mph speed limit. The ORV corridor would be adjusted whenever possible to allow vehicle passage. If the ORV corridor is not feasible for safety reasons or insufficient area, an alternate ORV route would be identified, if possible. If no alternate route is available, Seashore staff would consider establishing a bypass route. Under alternative A, Seashore staff would allow observations to be responsive to individuality in bird behavior when determining

adequate size of closure zones. As noted in chapter 3, a 3-year study on Cape Cod and Fire Island, New York (Kluft and Ginsberg 2009), found that higher ORV traffic resulted in dispersal and desiccation of the wrack line, thereby reducing the population of invertebrates in that area. Alternative A would allow for beach driving during the day outside of resource closures, with no restrictions on night driving. This level of access would result in long-term minor to moderate impacts expected to invertebrate populations (discussed later in this chapter), and therefore would reduce the food source to birds at the Seashore, resulting in long-term moderate impacts.

A temporary ORV bypass could be used under alternative A, but based on past management this would be expected to be an uncommon occurrence. Such bypasses, if established, would be far removed from piping plover territory as impacts to plovers from human disturbance are well documented in scientific literature and could result in direct mortality (Melvin et al. 1994; Patterson et al. 1991; Flemming et al. 1988; Lafferty 2001a) and behavioral changes (Lafferty 2001b), resulting in lower reproductive success (Zonick 2000; Burger 1991; Burger et al. 2004). These bypasses would not have an impact on piping plovers as they would be established in a manner that protects habitat and does not impede the brood from foraging.

Although buffers established under alternative A were designed to protect piping plover, as demonstrated in “Chapter 3: Affected Environment,” compliance with buffers, corridors, and closures is not absolute, which can result in people, vehicles, and pets in proximity to plovers and within plover habitat. Under alternative A, chances for non-compliance (either intentional or unintentional) would be increased as the buffers are variable based on chick behavior and could change frequently. Regular patrols of areas by law enforcement rangers, trained observers, and field biologists would help to deter closure violations. In addition, partnerships with local organizations would help to provide peer-based compliance with closures. However, under alternative A, there is an ORV corridor that provides a conduit or access to the Seashore and no closed ORV areas, so non-compliance would be more possible. A lack of compliance with resource protection closures, including non-compliance (intentional or unintentional) due to variable buffer sizes, could result in short-term moderate to major adverse impacts at a particular location, and would result in long-term moderate to major adverse impacts if there is a chronic lack of compliance.

*Night-Driving Restrictions.* Under alternative A, there would be no limitations on night driving. Plovers are known to be active at night (Staine and Burger 1994; Majka and Shaffer 2008), and plover chick response to vehicles can increase their vulnerability to ORVs (USFWS 1996a; 2009a). Allowing night driving under alternative A would result in long-term moderate adverse impacts as some impacts might occur during critical periods of reproduction and result in harassment, injury, or mortality to one or more individuals.

*Commercial Fishing.* Under alternative A, commercial fishing would be managed under special use permit. As part of this permit, terms and conditions would be placed on the permit holder, including a prohibition on entering resource closures. All other closures (safety and seasonal) would be accessible by commercial fishing permit holders. As resource closures would be off limits to commercial fishermen, there would be long-term negligible adverse impacts to piping plover from this use.

*Permitting/Carrying Capacity Requirements.* Under alternative A, there would be no permit or carrying capacity requirements placed on ORV users at the Seashore. A permit system would provide the Seashore with a method for dealing with non-compliance, as well as providing education to ORV users regarding piping plover habitat at the Seashore and its importance to the species. Lack of a permit system would have long-term moderate adverse impacts. Lack of a carrying capacity requirement is not expected to impact piping plover as ORVs would not be allowed in resource protection areas.

*Pet/Other Recreational Activity Restrictions.* Alternative A would prohibit camping, restrict beach fires to the hours of 6:00 a.m. to 12:00 a.m., and permit pets at the Seashore year-round, in accordance with 36 CFR 2.13. The prohibition of camping and restriction of beach fires would have long-term minor benefits to piping plover, as disturbance from these activities would be reduced. The presence of pets at the Seashore, including during breeding season, has the potential to adversely impact piping plover as some visitors to the Seashore do not observe the requirement for pets to be restrained in some manner, as observed by Seashore staff. If there is little or limited compliance with pet restrictions in the areas of closures, a negative effect on the plovers could result (USFWS 1996a; 2009a). This would be mitigated by the prohibition of pets from the landward side of the posts delineating the ORV corridor at the spits and Cape Point, the prohibition of pets within symbolic fencing around any bird closure area, and through education and outreach efforts via the Seashore field personnel and partnerships with local volunteers and organizations, but could still result in long-term minor to moderate adverse impacts, due to non-compliance.

*Overall Impacts from ORV and Other Recreational Use.* Overall, impacts to piping plover from ORV and other recreational use would be long-term moderate to major adverse as much of the Seashore would be open to recreational use, with an increased potential that piping plover could be impacted due to disturbance from ORV use and other recreational activities. Lack of a permit system for education and law enforcement, no night-driving restrictions, and lack of compliance with pet leash requirements would contribute substantially to these adverse impacts.

**Cumulative Impacts.** Past, present, and future actions discussed under the cumulative impact scenario could be expected to have a range of impacts on piping plover. Various dredging activities are occurring in the vicinity of the Seashore, such as the dredging of the federally authorized navigation channel at Oregon Inlet. These dredging activities fall under two categories, major dredging projects and maintenance activities. For the dredging of Oregon Inlet, major projects occur every four to five years, with sand being deposited in areas outside the Seashore, such as on Pea Island. Major dredging of Oregon Inlet is typically avoided during the breeding season; however, maintenance dredging does occur and could result in short-term minor adverse impacts due to disturbance. When major dredging projects do occur, it is common for piping plover foraging and nesting habitat at the southern end of Bodie Island Spit to slough off into the channel for a number of months after the dredging operation, which could cause minor to moderate adverse effects to piping plover.

Storms and other weather events during the piping plover breeding season (March–August) can result (depending upon storm intensity) in temporary displacement of and disturbance to nesting birds or even in the washing away or flooding of nests and eggs (Haig and Oring 1988; Houghton 2005; Cohen et al. in prep; Muiznieks pers. comm. 2009). In addition to the timing of summer storms, storm severity is also an important variable. Powerful storms can surge and overwash large areas of piping plover habitat including even up to the toe of the dune and beyond and result in loss of scrapes, nests, eggs, chicks, and even breeding adults. Conversely, winter, late fall, and early spring storms are capable of having benefits to piping plovers by depositing new materials and creating overwash areas and hence new nesting and foraging habitat for piping plovers or negative impacts by eroding and removing otherwise suitable habitat. Hence, the impacts of storms and piping plovers depend on the timing and severity of storm events and whether they result in piping plover habitat creation or destruction (Cohen et al. 2008).

Berm construction under the Civilian Conservation Corps (CCC) provided dune stabilization that changed the habitat available to piping plover at the Seashore. These stabilization efforts provided for the establishment of NC-12 and subsequent development, removing this area from potential habitat. These past actions resulted in long-term moderate adverse impacts to all shorebird species at the Seashore. Similarly, continual maintenance of NC-12 and berm maintenance would have a short-term, minor to moderate, adverse impact to the extent that it takes place during piping plover breeding season and if

maintenance results in encroachment on any nest buffers or resource closures, these impacts would be greater. If encroachment occurs, it could result in habitat loss that would have short-term, minor to moderate, adverse impacts to piping plover nesting and foraging. The degree to which this activity is negative is a function of the timing and location of the activity itself relative to piping plover nesting and the degree to which the activity results in the creation or stabilization of any high-quality piping plover habitat.

Hurricanes can also affect the piping plover because of their impact on staff resources. Storm recovery that pulls staff from resources management (including species monitoring or law enforcement) duties during piping plover breeding season would have adverse impacts. Conversely, hurricane recovery that takes place outside of the breeding season would have no direct effect on piping plover and could enhance piping plover habitat.

Commercial fish harvesting would have negligible impact on piping plovers because plovers do not feed on any commercially important fish. However, plovers do feed on some of the same prey items of fish species that may be harvested and, as such, harvest of fish may mean greater prey encounters for plovers. In this case, the impact of commercial fishing could result in long-term minor to moderate increases in prey availability that would have a beneficial impact on piping plover foraging.

Several of the local and NPS past, current, and future planning efforts can also affect locally sensitive bird species. For example, new development that has occurred in Dare and Hyde counties under their land use plans had increased the residential housing and related services in the areas within the Seashore. This land development within the Seashore, as well as throughout the counties, has reduced the amount of habitat available to species, resulting in adverse impacts. In addition to past actions, new development could result from the implementation of the County Land Use Development Plans for Dare and Hyde counties, including expected revisions to the Dare County Plan. The details of any plan revisions are not certain and the potential for impacts on piping plovers is indeterminate at this time. If increased development within the Seashore's boundaries would result from the implementation of these plans and increase recreational use of the beaches, adverse impacts to plovers could occur.

The education component of the Seashore's Long-Range Interpretive Plan would provide long-term minor to moderate benefits as it would help to educate visitors about the conservation needs of the birds that inhabit the Seashore and the conservation measures enacted to help protect them.

Current predator control and the Predator Management Plan would provide long-term major benefits by helping to control mammalian predators, such as fox and others, which prey upon plover adults, eggs, and young. Continuing to remove fox (both red and gray fox), raccoons, cats, and other predators from the Seashore and continuing to use predator exclosures would be beneficial to the piping plover. However, predator management actions such as the placement and checking of predator exclosures and traps would bring people, essential vehicles, and equipment into direct contact with piping plovers and their habitat because actions and some essential vehicle traffic would occur inside the established buffer. This could cause short-term minor adverse impacts. Predator trapping might result in short-term minor disturbance to nests and young, or result in loss of nests or hatchlings if trappers are not cognizant of nest locations. However, overall predator management actions would be highly beneficial.

The Cape Lookout Interim Protected Species Management Plan/EA provides long-term moderate to major beneficial impacts to piping plover at the neighboring Seashore through the management policies that it employs. However, even with those management measures in place, adverse impacts would still occur to the species as recreational uses, including night driving, would still occur, but would be mitigated to an extent by the management measures being employed. The measures that are in place now under the interim plan increase protections, in part, by providing earlier prenesting closures and allowing

for buffers for protected species to expand if needed, as noted in the Cape Lookout Interim Protected Species Management Plan/EA. The outcome of the Cape Lookout National Seashore ORV Management Plan/EIS would also have direct long-term impacts on bird populations within the Seashore, as well as within the state of North Carolina. Specifically, it would have an impact on the region's goal of achieving compliance with the Piping Plover Recovery Plan (USFWS 1996a). However, whether the impact of the ORV plan would be moderate to major beneficial or adverse to piping plovers would depend upon the management decisions that are made and ultimately implemented.

The replacement of the Herbert C. Bonner Bridge would occur in the vicinity of the Seashore. An EIS and Biological Opinion for this project found, "the proposed replacement of the Bonner Bridge... as proposed, is not likely to jeopardize the continued existence of these species [including piping plover], and is not likely to destroy or adversely modify proposed critical wintering habitat for the piping plover." Given these findings, this project would be expected to result in short-term negligible adverse impacts to piping plovers if minimal disturbance from construction noise and lighting to courting, nesting, and foraging plovers would potentially be experienced.

The overall cumulative impacts of these past, current, and future actions would be long-term negligible to minor, depending on the intensity and duration of unpredictable factors such as storm events, with long-term moderate beneficial impacts from actions such as increased interpretive programs as part of the long-range interpretive plan and predator management within the Seashore. Many of these actions do not directly impact piping plover habitat in the area, as most of this habitat is located within the Seashore and is impacted by NPS management actions more than any of the aforementioned past, present, and future actions. These impacts, combined with the impacts of alternative A, would be long-term moderate to major adverse, as actions within the Seashore would act as a driver for overall cumulative impacts.

**Conclusion.** Overall, impacts to piping plover from resources management activities would be long-term minor to moderate adverse. Although the management of the species would provide a certain level of benefit, the manner in which buffers would be established, along with the need to adjust buffers frequently, would have an adverse impact on the species. Overall, impacts to piping plover from ORV and other recreational use would be long-term moderate to major adverse as much of the Seashore would be open to recreational use, with an increased potential that piping plover could be directly impacted by disturbance from recreational activities. Lack of a permit system for education and law enforcement purposes, no night-driving restrictions, and lack of compliance with pet leash requirements would contribute substantially to these adverse impacts. The impacts to piping plover under alternative A (and all other alternatives) are shown in table 52.

Cumulative impacts under alternative A would be long-term moderate to major adverse.

**Determination of Effect.** Under the ESA, the actions taken under alternative A may affect / are likely to adversely affect piping plover due to the minor adverse effects from monitoring and surveying and from moderate to major adverse effects of ORV and other recreational use, including the potential for an increase in the presence of pets and predators that often accompany recreation/ORV use. ORV and other recreational use could result in short- and long-term moderate to major adverse impacts, especially with the high level of non-compliance that could result from buffers that adjust often and unpredictably. Further, the lack of night-driving restrictions could contribute to long-term moderate adverse impacts to plovers under alternative A as they are known to forage on the shoreline during all hours. These impacts would result in a finding of may affect/ are likely to adversely affect piping plovers under the ESA because the action would result in direct or indirect impacts to the species that are not discountable, insignificant, or beneficial. And while there may be beneficial impacts from species monitoring and surveying, and management of recreation, the actions under alternative A would also likely result in adverse effects.

Under the ESA, the actions taken under alternative A may affect / are likely to adversely affect designated critical habitat for wintering piping plover due to the level of recreational access provided within these critical habitat areas and the impact of that access on the value of the habitat. There would be long-term, minor beneficial effects from closing suitable interior habitats at spits and at Cape Point to all recreational users, as these interior habitats are considered one of the PCEs that comprise the designated critical habitat for wintering piping plover. However, year-round recreational use would continue to occur on the majority of the intertidal sand beaches, spits, and backshore, which are also PCEs of designated critical habitat. The level of recreational use (through the designation of the majority of the Seashore an ORV route or area year-round) could result in vehicular and pedestrian disturbance to foraging plovers and a reduction of invertebrate prey due to disturbance or destruction of the wrack from vehicles driving in and around the wrack. Although this alternative would not result in a direct loss of critical habitat, the impacts of recreational use would result in a reduction in the value of the designated critical habitat for wintering plovers.

Implementation of alternative A would result in a finding of may affect / is likely to adversely affect designated critical habitat for wintering piping plover under the ESA because the action would result in direct or indirect impacts to the critical habitat for the species that are not discountable, insignificant, or beneficial. And while there would be beneficial impacts from the protection of suitable interior habitat, there would be adverse effects on the value of the primary constituent elements of critical habitat, due to the majority of spits, intertidal sand beaches, and ocean backshore being open to recreational use during wintering.

### **Impacts of Alternative B: No Action—Continuation of Management under Terms of the Consent Decree**

#### **Resources Management Activities**

*Establishment of Prenesting Closures.* Under alternative B, piping plovers would likely benefit from the increased surveying and resultant closures in the prenesting phase. Specifically, in February or early March of each year, Seashore staff would conduct an annual assessment of piping plover breeding habitat and implement prenesting closures in recent breeding areas by posting symbolic fencing by March 15. The prenesting areas would not be reduced to accommodate an ORV corridor, including in the event of naturally occurring erosion or accretion of the area, except in emergency situations. The closures would remain in place until the later of July 15 or two weeks after the last piping plover, tern, black skimmer, American oystercatcher, or Wilson's plover chick within the area has fledged, as determined by two consecutive monitoring events. The establishment of these closures earlier in the season would ensure those piping plovers arriving early are afforded protective buffers, and would result in long-term moderate benefits for the species.

*Surveying and Monitoring.* Under alternative B, surveying would follow guidelines in the 1996 USFWS Piping Plover Recovery Plan, as well as survey procedures identified in the Interim Strategy, as modified by the consent decree. Seashore staff would survey piping plover habitat at Cape Point, South Beach, Hatteras Inlet Spit, North Ocracoke Spit, and South Point at least once every two days from March 15 to April 15, and daily from April 16 to July 15, to determine if any birds are exhibiting prenesting and/or breeding behavior. The Seashore would monitor Bodie Island Spit at least daily from March 15 to July 15. Potential new habitat, if any, at other locations would be surveyed two times per week.

By surveying the historic areas and new potential habitat beginning March 15, the likelihood that any piping plovers establishing territories in these areas would be detected increases. Observations of piping plover in these areas would continue until at least July 15, which would positively affect plovers that might not establish nests until later in the season. Prenesting areas would be left in place until July 15 or

two weeks after all chicks of any species in the area have fledged, whichever occurs later. Other buffers for piping plovers (e.g., buffers installed based on observed breeding or foraging behavior) would be removed two weeks after the last observed activity, or after chicks have fledged.

Surveying would bring people and/or essential vehicles into direct short-term contact with piping plovers and their habitat, and these activities themselves are a known risk factor, especially during the more sensitive life stages of early prenesting and territory establishment. However, many precautions would be taken by staff to minimize impacts, for example, using scopes to watch the birds from a distance and remaining outside closures to the extent possible, and the protection that results from surveying would result in long-term moderate beneficial impacts, as any changes in species behavior would be detected and appropriate management measures implemented.

*Buffer/Closure Establishment.* Under alternative B, if breeding behavior, including but not limited to territorial behavior, courtship, mating, confirmed scrapes, or other nest building activity, or breeding adult piping plover foraging occurs outside of an established closure, Seashore staff would establish a 50-meter (164-foot) buffer around the observed activity. If disturbance from ORVs and/or pedestrians occurs within the given buffer distance, the buffer zone would be expanded in 50-meter (164-foot) increments until no disturbance occurs. Behaviors indicating disturbance would include defensive displays, alarm calls, flushing, leaving a nest or feeding area, or diving and mobbing pedestrians, dogs, or vehicles. Deliberate acts of vandalism or acts that result in disturbance to bird behavior would result in an automatic expansion of prenesting areas or buffers in increments of 50 meters, 100 meters, and 500 meters.

If buffers are expanded for any of the reasons stated above, the ORV corridor would not be adjusted to accommodate ORV use. For observed piping plover prenesting and/or breeding behavior, NPS would establish the prescribed buffers as quickly as possible, but always within eight daylight hours. Upon discovery of an active nest or chicks that are outside an existing closure, protective measures would be taken immediately to close and establish the buffers described above. Symbolic fencing with the applicable buffer distances stated above would be installed as soon as Seashore staff can reasonably be mobilized to install the fencing, but always within six daylight hours.

Under alternative B, all broods would be observed in the mornings and late afternoons; however, buffer distances for piping plover chicks would be substantially larger for the first two weeks after hatching and may sometimes stay in effect until fledging. The larger buffers would be longer lasting under Alternative B, and would result in moderate benefits to piping plover chicks. The size of buffers for piping plover chicks could be reduced after two weeks, but special monitoring provisions would apply, as described in the next section.

Alternative B provides for protection of piping plover nests through the use of buffer distances recommended under the Piping Plover Recovery Plan (USFWS 1996a). Further, additional information would be collected during this life stage from daily observations via use of optical equipment from an adequate distance to prevent disturbance and from close approaches to nests once per week to visually inspect the nest and check on the enclosure. Staff observing bird location and behavior would implement the prescribed buffers as a minimum, but would have the flexibility to increase the size of closures, as some individual piping plovers may require larger buffers than others (USFWS 1996a; 2009a). Except for the potential disturbance caused by the once per week nest examination, the larger and more responsive buffers under alternative B would be expected to have long-term minor to moderate beneficial effects on the species as Seashore personnel and recreationists who respect resource closures would be kept a safe distance from incubating adults and their nests.

*Management of Wintering/Nonbreeding Populations.* As provided in the USFWS Amended Biological Opinion (USFWS 2007a) and described in alternative A, Seashore staff would monitor the presence, abundance, and behavior of migrating and wintering piping plovers from August 1 to March 31 of each year following the SECN survey protocol, and close suitable habitat as described under alternative A. These closures would provide beneficial impacts to species during this life stage, as described under alternative A, and the addition of a surveying plan would provide Seashore managers with information on the types and locations of habitats used, seasonality of plover use of the Seashore, tidal influence on habitat use, and potential threats the habitat may contain. Surveying would increase knowledge on how and when piping plovers use the Seashore and enable adaptive management initiatives. These actions would result in long-term moderate beneficial impacts.

*Education and Outreach.* Under alternative B and as described under alternative A, the public would continue to receive information at the visitor centers about piping plovers and their ecology and the measures the Seashore is taking to protect the species. In addition, the Seashore would provide public education by posting protected species information at all access points. As with alternative A, public outreach as part of species management would have long-term minor beneficial impacts, with the expanded outreach having greater impacts than alternative A.

*Overall Impacts of Resources Management Activities.* Overall, impacts under alternative B from resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term minor to moderate beneficial. Buffers for piping plover would be larger and provide more protection compared to buffers under alternative A. Minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of prenesting closures early in the breeding season, monitoring activities, education and outreach efforts, and establishment of prescribed buffers would provide long-term minor to moderate beneficial impacts to the species.

### **ORV and Other Recreational Use**

*ORV and Pedestrian Access.* Under alternative B, management of ORV and pedestrian access at the Seashore would be a continuation of management under alternative A, except where modified by specific species protection measures from the April 30, 2008, consent decree. These management modifications include installation of prenesting areas by March 15 (two weeks earlier than under alternative A), increasing the size of some of the buffers provided to various species at the Seashore, as well as restrictions imposed related to night driving. Specifically, ORV corridors under alternative B are the same as alternative A, except that from March 15 to November 30 at all locations not in front of the villages that are open to ORV use, NPS would provide an ORV-free zone in the ocean backshore at least 10 meters wide, wherever there is sufficient beach width to allow an ORV corridor of at least 20 meters above the mean high tide line. As noted in chapter 3, a 3-year study on Cape Cod and Fire Island, New York (Kluft and Ginsberg 2009), found that higher ORV traffic resulted in dispersal and desiccation of the wrack line, thereby reducing the population of invertebrates in that area. Alternative B would allow for beach driving in the wrack during the day in areas of the Seashore open to ORV use (not within resource closures), but would maintain nighttime closures reducing disturbance in this area at night for a portion of the year. Overall impacts to invertebrates would be long-term and minor (as discussed later in this chapter), and would reduce the food source available to birds at the Seashore, but to a lesser degree than if night driving was permitted, resulting in long-term minor impacts.

Alternative B would designate the all the ocean and inlet shoreline and the existing soundside routes as ORV routes or areas year-round, subject to temporary resource closures, seasonal ORV closures in front of the villages, and temporary ORV safety closures (see figure 2, chapter 2, alternative A and B maps), and would provide for closures of piping plover prenesting areas, as well as closures based on observations of breeding behavior, foraging, and chick movement. Alternative B would designate an

approximately 100-foot (30-meter) wide ORV corridor above the mean high tide line outside of prenesting areas in breeding areas used within the past three years. The speed limit on Seashore beaches would be 15 mph from May 15 to September 15, unless otherwise posted; and 25 mph from September 16 to May 15, unless otherwise posted. Under alternative B and as described in the previous section, staff would monitor piping plover habitat for signs of breeding behavior and human disturbance, ensure the timely installation of resource closures, and ensure adequacy of prescribed buffers. Resource closures, including prenesting areas, would not be adjusted to accommodate ORV use.

Impacts to plovers from human disturbance are well documented in scientific literature and could result in direct mortality (Melvin et al. 1994; Patterson et al. 1991; Flemming et al. 1988; Lafferty 2001b; Page et al. 2009) and behavioral changes resulting in lower reproductive success (Zonick 2000; Burger 1991; Burger et al. 2004). Alternative B is designed to redirect ORV routes and corridors to areas that would not impact the brood, and any ORV route would be closed if it were within 1,000 meters (3,281 feet) of a brood. Trained Seashore staff in the area would be able to monitor bird behavior, as well as observe acts of disturbance. Through contact on the beach, websites, posted information at access points, and information available at the visitor centers, the public would be informed of alternate routes and ways to reduce their effect on the plovers (e.g., removing trash, reduced speed limit, etc.).

If Seashore staff observes disturbance of piping plovers from ORV or pedestrians, the buffer zone would be expanded in 50 meter increments until no disturbance occurs. When piping plover chicks are present, an ORV closure area would extend for 1,000 meters (3,281 feet) on each side of a line drawn through the nest site and perpendicular to the long axis of the beach for the first two weeks after hatching. The resulting ORV closure would extend from the oceanside low water line to the soundside low water line or the dune line if no soundside habitat exists, and ORV use would be prohibited in these areas. Under alternative B, a pedestrian buffer of 300 meters would be established when chicks are present.

ORVs may be allowed to pass through portions of the protected area, where the protected area is considered by Seashore staff to be inaccessible to piping plover chicks because of steep topography, dense vegetation, or other naturally occurring obstacles. All of the ocean beach at Cape Point, South Beach, and North Ocracoke Spit and the entire soundside and ocean beach at Bodie Island Spit and South Point would be considered accessible to piping plover chicks. Within the 1,000-meter piping plover unfledged chick buffer at Hatteras Inlet Spit, all of the ocean beach and that part of the soundside beach at the overwash fans and from the inlet east to a point 200 meters east of the point where the Spur Road from the Pole Road meets the sound would be considered accessible to piping plover chicks in these areas.

Under alternative B, during daylight hours only, Seashore staff may allow ORV access within the 1,000-meter unfledged piping plover chick buffer two weeks after the chicks have hatched. When ORV access is allowed, a buffer distance of 300 meters between piping plover chicks and ORVs would be maintained at all times. The chicks would be monitored from dawn to dusk by Seashore staff with at least one full season of experience monitoring piping plovers or snowy plovers. The modified access area would not be open to ORVs each morning until the location of the brood has been determined by a qualified monitor and an adequate buffer has been assured. If a piping plover adult or chick moves within 200 meters of ORVs or an ORV access corridor, Seashore staff on site would immediately take protective measures to close the access corridor and re-establish the 1,000-meter buffer, including contacting law enforcement to begin evacuation of the area; no additional nonessential ORVs would be allowed within the 1,000-meter unfledged piping plover chick buffer. NPS would retain the discretion to re-establish the 1,000-meter buffer at any time, if it deems the full closure to be necessary. Locations of the described buffers would be adjusted to accommodate chick movement.

Given the increased level of monitoring at the key piping plover breeding areas and the significantly larger buffers when piping plover chicks are present, alternative B would offer more protection from recreational use than alternative A. However, due to all the ocean and inlet shoreline and the existing soundside routes of the Seashore being designated as an ORV route, the potential for impacts to piping plover from recreational use would still exist, resulting in long-term moderate adverse impacts.

*Night-Driving Restrictions.* Under alternative B, night driving of all recreational ORV traffic would be prohibited from 10:00 p.m. until 6:00 a.m. from May 1 to September 15. However, from September 16 to November 15, night-driving permits would be available for authorized nonessential driving between the hours of 10:00 p.m. and 6:00 a.m. The permit has an educational component, and the permit would contain restrictions on light use during the September 16 to November 15 permitted night-driving period. Furthermore, NPS retains the discretion to limit night driving to certain areas or routes, based on resource protection considerations. Because plovers are known to be active at night (Staine and Burger 1994; Majka and Shaffer 2008), and plover chick and fledgling response to vehicles can increase their vulnerability to ORVs (USFWS 1996a, 2009a), seasonal restrictions on night driving under alternative B would provide long-term minor to moderate benefits to piping plovers; however, alternative B could still result in long-term minor adverse impacts during times when night driving is permitted (until 10:00 p.m. May 1 – September 15 and all nighttime hours from September 16 through April 30).

*Commercial Fishing.* Commercial fishing restrictions under alternative B would be the same as those under alternative A, with those holding commercial fishing permits restricted from night driving from 10:00 p.m. until 5:00 a.m. (as opposed to 6:00 a.m. for recreational users) from May 1 to September 15. As with recreational users, commercial fishing permit holders can get a permit for night driving from September 16 to November 15. Presence of commercial fishing operations would have a long-term negligible adverse impact to piping plovers, with long-term minor to moderate beneficial impacts occurring due to night-driving restrictions.

*Permit/Carrying Capacity Requirements.* As described above under the night-driving restrictions and education/outreach sections, alternative B would require a night-driving permit from September 16 to November 15. As stated in these sections, the night-driving permit applies after the piping plover breeding season is over and would have no impact on the species protection offered from these elements. There would be no impacts related to carrying capacity, as it would not be a requirement under alternative B.

*Pet/Other Recreational Activity Restrictions.* Alternative B would have the same restrictions on camping, beach fires, and pets as alternative A, although no ORV use would be allowed from 10:00 p.m. to 6:00 a.m. between May 1 and September 15. As with alternative A, there would be the potential for non-compliance with pet regulations, although the presence of law enforcement and other Seashore staff would help ensure compliance with the pet leash requirement. Education and outreach efforts of Seashore staff would help minimize adverse impacts and would result in long-term minor to moderate adverse impacts, due to the potential for non-compliance.

*Overall Impacts from ORV and Other Recreational Use.* Overall, impacts to piping plover from ORV and other recreational use would be long-term moderate adverse. While some buffers would be increased in an attempt to separate recreational uses from piping plover, access up to these buffers would be provided at all Seashore beaches and could result in intentional or unintentional non-compliance (i.e., when signs are washed out), which would impact the species. Adverse impacts would also occur due to limited prenesting protection outside of the points and spits, and the potential for protective buffers to be reduced during critical life stages of plover chicks.

**Cumulative Impacts.** The past, present, and future actions discussed under the cumulative impact scenario for alternative A would be expected to be the same under alternative B. The overall cumulative impacts of these past, current, and future actions, would be long-term negligible to minor, depending on the intensity and duration of unpredictable factors such as storm events, with long-term moderate beneficial impacts from actions such as increased interpretive programs as part of the long-range interpretive plan and predator management within the Seashore. Many of these actions do not directly impact piping plover habitat in the area, as most of this habitat is located within the Seashore and is impacted by NPS management actions more than any of the aforementioned past, present, and future actions. These impacts, combined with the impacts of alternative B, would be long-term moderate adverse, as actions within the Seashore would act as a driver for overall cumulative impacts.

**Conclusion.** Overall impacts under alternative B from resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term minor to moderate beneficial. Buffers for piping plover would be larger, and would provide more protection compared to those under alternative A, resulting in less of an adverse impact. The benefits from the prenesting closures, along with the benefits from increased surveying and monitoring efforts, would result in long-term minor to moderate beneficial impacts to piping plover. Minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of prenesting closures early in the breeding season, monitoring activities, education and outreach efforts, and establishment of prescribed buffers would provide long-term minor to moderate beneficial impacts to the species. Overall, impacts from alternative B to piping plover from ORV and other recreational use would be long-term moderate adverse. While some buffers would be increased and more constant to keep recreational uses separated from the species, access up to these buffers would be provided throughout the Seashore and could result in intentional or unintentional non-compliance, which would adversely impact the species. Adverse impacts would also occur due to the substantial amount of beach mileage open to ORV use year-round, limited prenesting protection outside of the points and spits, and the potential for protective buffers to be reduced during critical life stages of plover chicks.

Cumulative impacts to piping plover under alternative B would be long-term moderate adverse.

**Determination of Effect.** Under the ESA the actions taken under alternative B may affect / are likely to adversely affect piping plover due to the minor adverse effects from monitoring and surveying and from the moderately adverse impacts from ORV and other recreational use, especially with the high level of non-compliance that could result from buffers that adjust often and unpredictably. Further, the partial night-driving restrictions could contribute to long-term minor to moderate benefits to piping plovers, but could still result in long-term minor adverse impacts during the time when night driving is permitted (until 10:00 p.m. May 1 – September 15 during the piping plover breeding season) under alternative B as plovers are known to forage the shoreline during all hours (Cohen et al. 2008). These impacts would result in a finding of may affect/ are likely to adversely affect piping plovers under the ESA because the action would result in direct or indirect impacts to the species that are not discountable, insignificant, or beneficial. And while there may be beneficial impacts from monitoring, surveying and management of recreation, the actions under alternative B would also likely result in minor adverse impacts from human presence during monitoring activities.

Under the ESA, the actions taken under alternative B may affect / are likely to adversely affect designated critical habitat for wintering piping plover due to the level of recreational access provided within these critical habitat areas and the impact of that access on the value of the habitat. There would be long-term, minor beneficial effects from closing suitable interior habitats at spits and at Cape Point to all recreational users, as these interior habitats are considered one of the PCEs that comprise the designated critical habitat for wintering piping plover. However, year-round recreational use would continue to occur on the majority of the intertidal sand beaches and spits, which are also PCEs of designated critical habitat. The

level of recreational use (through the designation of the majority of the Seashore an ORV route or area year-round) could result in vehicular and pedestrian disturbance to foraging plovers and a reduction of invertebrate prey due to disturbance or destruction of the wrack from vehicles driving in and around the wrack. There would be some benefit to the critical habitat from the implementation of seasonal night-driving restrictions although these restrictions would only apply between May 1 and November 15, which would not cover the majority of time when the wintering population of piping plover is present at the Seashore. Similarly, the protection of ocean backshore (also a PCE) under alternative B would not be required during the peak wintering period for piping plover and would not be implemented in areas of narrow beach width. Although this alternative would not result in a direct loss of critical habitat, the impacts of recreational use would result in a reduction in the value of the designated critical habitat for wintering plovers.

Implementation of alternative B would result in a finding of may affect / is likely to adversely affect designated critical habitat for wintering piping plover under the ESA because the action would result in direct or indirect impacts to the critical habitat for the species that are not discountable, insignificant, or beneficial. And while there would be beneficial impacts from the protection of suitable interior habitat, there would be adverse effects on the value of the primary constituent elements of critical habitat, due to the majority of spits, intertidal sand beaches, and ocean backshore being open to recreational use during wintering.

### **Impacts of Alternative C: Seasonal Management**

#### **Resources Management Activities**

*Establishment of Prenesting Closures.* Prenesting surveying activities for piping plovers under alternative C would include the survey and evaluation of all potential breeding habitats by Seashore staff by March 1 of each year with piping plover prenesting closures recommendations based on that evaluation.

Alternative C would establish SMAs, which are defined as areas of suitable habitat that have had concentrated and recurring use by multiple individuals and/or multiple species of protected shorebirds during the breeding or nonbreeding season (details are provided in “Table 10, Species Management Strategies for Action Alternatives” in chapter 2). Under alternative C, all designated breeding SMAs would be posted as prenesting closures using symbolic fencing by March 15 each year. The SMAs would be designated for two different MLs, ML1 or ML2. Under ML1, ORV or pedestrian access would not be allowed while prenesting closures are in effect. Under ML2, once prenesting closures are implemented, a narrow pedestrian access corridor would be established. Under alternative C, Bodie Island Spit, Cape Point, and South Point would be established as SMAs and managed under ML2. The remaining SMAs (and areas outside of SMAs) would be managed under ML1 measures. The prenesting closures, as well as the establishment of SMAs, would have long-term moderate beneficial impacts as closures would be in place to protect migrant piping plovers and birds establishing territories early in the breeding season.

*Surveying and Monitoring.* From March 15 through July 15, areas within any prenesting closures would be monitored three times per week and areas outside of any prenesting closures would be monitored two times per week, which would be increased to three times per week if birds are detected during monitoring. Seashore staff would look for piping plover nests by conducting “walk throughs” every three days. Once piping plover nests are found they would be observed daily from a distance that does not disturb the birds, based on professional judgment. Nests would be approached once per week to visually inspect the nest and check on the exclosure. Alternative C would include surveying all suitable breeding habitat three times a week to detect adults with an associated scrape area or nest foraging outside of an existing closure, which would allow for potential closures for foraging in the areas near known breeding sites. If breeding adult piping plover are observed foraging outside of an existing closure, the site would be surveyed daily to look for signs of courtship and/or nesting building. If piping plover are observed

foraging outside of a closure on two consecutive surveys, a buffer would be either established or expanded using flexible increments based on observed bird behavior to include the entire length of the foraging site. These foraging area closures would be removed if no piping plover foraging is observed for a two-week period during the breeding season, or when any associated breeding activity has concluded. Under alternative C, piping plover nests and/or chicks would be surveyed and those with broods under ML1 management would be observed at least once a day, and broods under ML2 management would be observed daily for at least one hour in the morning and one hour in the afternoon. Monitor(s) would be present during all periods of ORV or pedestrian access. Observations under ML1 and ML2 management would end once chicks have fledged (chicks are considered fledged at 35 days of age or are observed in sustained flight of at least 49 feet [15 meters]). Surveying and monitoring as described above would increase knowledge on how and when piping plover use the Seashore and thereby enabling the NPS to implement adaptive management initiatives, providing a beneficial impact. However, as with all the alternatives, surveying and monitoring would bring people and/or essential vehicles into direct short-term contact with piping plovers and their habitat, and these activities themselves are known risk factors, especially during the more sensitive life stages of early prenesting and territory establishment. Under alternative C, many precautions would be taken by staff to minimize impacts from monitoring such as using high powered scopes and thereby reducing impacts from intrusion by monitors. The impact of the monitoring when these precautions are taken into consideration would be minor. Although there would be adverse impacts such as disturbance to piping plover at various life stages, the protection that would result from surveying would result in long-term moderate beneficial impacts, as these actions would improve the sustainability of the species at the Seashore.

*Buffer/Closure Establishment.* Under alternative C, during the breeding season, ML1 measures would be implemented at South Beach, Hatteras Inlet Spit, and North Ocracoke Spit, and ML2 measures would be implemented at Bodie Island Spit, Cape Point, and South Point. Both ML1 and ML2 would provide 75-meter buffers around any piping plover nests, nest scrapes, and around any piping plover exhibiting breeding behavior. ML2 differs from ML1 in that it establishes a narrow pedestrian access corridor. Upon the first observation of breeding activity, the standard buffers would apply, which depending upon the circumstance could close the access corridor. NPS would retain the discretion to expand nest buffers under ML1 and ML2, depending on staffing and bird behavior. In unprotected areas, a buffer would be established immediately when a nest with egg(s) is found. Prior to hatching, vehicles may pass by such areas within designated ORV access corridors that have been established along the outside edge of nesting habitat, provided that buffers adequate to prevent human disturbance are maintained. When nests or chicks occur in the immediate vicinity of paved roads, parking areas, campgrounds, buildings, and other facilities, NPS would retain the discretion to provide resource protection to the maximum extent possible while still allowing those facilities to remain operational. NPS would not reduce buffers to accommodate ORV ramp access under alternative C. Under alternative C, buffers would remain in place for two weeks after a nest is lost to determine if birds would re-nest. Outside of prenesting areas, piping plover buffers would be removed if no breeding activity is seen in the area for two weeks, or two weeks after all chicks have fledged, whichever comes later. For unfledged piping plover chicks, ML1 would provide a 1,000-meter buffer for ORVs and pedestrians, and ML2 would provide a 1,000-meter buffer for ORVs and a 300-meter pedestrian buffer. This buffer would move with the chicks and would extend from the oceanside low water line to the soundside low water line or to the farthest extent of dune habitat if no soundside intertidal habitat exists.

Piping plovers would likely experience long-term moderate benefits from the size of the resource closures under ML1 and ML2 and the fact that buffers would adjust in response to chick mobility, as these actions would be expected to improve the sustainability of the species at the Seashore.

Under alternative C, broods under ML1 would be observed once per day and broods under ML2 would be observed for a minimum of one hour in the morning and one hour in the afternoon, whereas under

alternative A broods would be observed continually during daylight hours during the first week and thereafter if the buffer size is 600 meters or less, or daily if the buffer is increased. Under alternative B, a 1,000-meter buffer would be established for the first two weeks after hatching and the brood would be observed for a minimum of one hour in the morning and one hour in the afternoon. If the buffer is reduced to 300 meters after the first two weeks then the brood would be monitored from dawn to dusk until fledging.

In addition to the establishment of prenesting areas, alternative C provides for protection of piping plover nests outside of the SMAs through the use of buffer distances recommended, in part, under the Piping Plover Recovery Plan (USFWS 1996a). Deviation from these recommendations and establishment of a 75-meter buffer around known nests is based on studies that show a greater susceptibility to disturbance in similar environments and Seashore staff observation (see “Elements Common to All Action Alternatives,” in chapter 2). Although the species would be offered protection by these buffers, short-term adverse impacts could result to piping plover if adjustments to a buffer are not made in a timely manner or if nests or acts of deliberate disturbance are missed by NPS staff outside of the SMAs. Therefore, the buffers under alternative C would be expected to have long-term moderate beneficial effects on the species because the benefits would outweigh the adverse effects.

Management conducted during prenesting and nesting life stages would bring people and/or essential vehicles into direct long-term contact with piping plover and their habitat, and these activities themselves are known risk factors, especially during the sensitive, early life stages of prenesting and territory establishment. However, management also results in providing appropriate protection to piping plover during these early stages of the annual nesting cycle that would otherwise expose piping plover to disturbances from a variety of activities that might do them far more harm and/or result in nest abandonment or abandonment of the area by the individual or pair. Hence, management provides long-term minor to moderate beneficial impacts to piping plover.

A systematic review of data, annual reports, and other information would be conducted by Seashore staff every 5 years, after a major hurricane, or if necessitated by a significant change in protected species status (e.g., listing or de-listing), in order to evaluate the effectiveness of management actions in making progress toward the accomplishment of stated objectives. Periodic review could result in changes to the management actions in order to improve effectiveness. When desired future conditions for resources are met or exceeded, periodic review and adaptive management may allow for more flexible management of recreational use, provided adverse impacts of such use are effectively managed and wildlife populations remain stable. Where progress is not being made toward the attainment of desired future conditions, periodic review and adaptive management may provide for additional management including appropriate restrictions on recreational use. Periodic review could result in changes to the management actions in order to improve effectiveness, which would have long-term moderate beneficial impacts.

*Management of Wintering/Nonbreeding Populations.* During the nonbreeding season, Seashore staff would monitor presence, abundance, and behavior of migrating and wintering shorebirds in all SMAs from July through May using the SECN protocol. These surveys would result in moderate beneficial impacts to plovers by providing Seashore managers with information on the types and location of habitats used by nonbreeding piping plovers, seasonality of plover use of the Seashore, tidal influences on habitat use, and potential threats the habitat may contain. Surveying would increase knowledge on how and when piping plovers use the Seashore and enable adaptive management initiatives.

During the nonbreeding season under alternative C, SMAs would be established at the points and spits based on an annual habitat assessment. In addition, year-round VFAs along the ocean shoreline outside of the villages would be managed as Nonbreeding Shorebird SMAs with recreational activity restrictions such that if staff determines that any single recreational activity or collection of activities is negatively

impacting nonbreeding piping plover use of a specific location, NPS may implement additional restrictions on activities. Regarding timing, under alternative C, all SMAs are closed to ORVs from March 15 through October 14, and a pedestrian access corridor is established at Bodie Island Spit, Cape Point, and South Point on March 15 (subject to ML2 actions when breeding activity is observed).

As with management that takes place during prenesting incubation and brood rearing life stages, post-breeding management conducted during the nonbreeding life stages would bring people and/or essential vehicles into direct long-term contact with piping plover and their habitat, and these activities themselves are known to result in disturbance to foraging and resting plovers. However, management also results in providing some protection to piping plover during nonbreeding life history stages that might otherwise expose piping plover to far more disturbances. Although migrant plover can and do utilize the entire shoreline, a large portion of the preferred stopover sites (i.e., Bodie Island Spit and South Point) remain closed to ORVs throughout the period when migrants are observed in the spring and fall and throughout the winter for the small population that overwinters at the Seashore. Hence, nonbreeding management protocols under alternative C provide long-term moderate beneficial impacts to nonbreeding piping plover.

*Education and Outreach.* Under alternative C, education and outreach activities would be the same as those described under alternative A, with the addition of educational requirements as part of a permit program. This additional education would result in long-term minor to moderate benefits to species as the public is provided with more information regarding this issue.

*Overall Impacts of Resources Management Activities.* Overall impacts under alternative C from resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term moderate beneficial. As with alternative B, minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of SMAs early in the breeding season, monitoring activities, and establishment of prescribed buffers would provide long-term moderate beneficial impacts to the species.

### **ORV and Other Recreational Use**

*ORV and Pedestrian Access.* Under alternative C, areas of high resource sensitivity (SMAs) and high visitor use would generally be designated as VFAs during the breeding season and peak visitation period (March 15 to October 14). ORV routes would be designated outside of these locations and would be open to ORV use during the same period. Some areas would be open to ORV use during the off-season (October 15 to March 14), while some areas would remain vehicle free year-round to provide opportunities for visitors to experience the Seashore without the presence of vehicles. The establishment of SMAs and other VFAs would serve to reduce pressure on the species from recreational uses, as compared to alternatives A and B. As noted in chapter 3, a 3-year study on Cape Cod and Fire Island, New York (Kluft and Ginsberg 2009), found that higher ORV traffic resulted in dispersal and desiccation of the wrack line, thereby reducing the population of invertebrates in that area. Alternative C would allow for beach driving in the wrack on ORV routes during the day outside of SMAs, but would maintain nighttime closures and limit driving during the day where SMAs are established reducing disturbance in these areas. Overall impacts to invertebrates would be long-term and negligible to minor (as discussed later in this chapter), and would reduce the food source available to birds at the Seashore, but to a lesser degree than if night driving was permitted, resulting in long-term minor impacts.

Approximately 27 miles of shoreline would be designated for ORV use year-round, approximately 27 miles would be seasonally designated for ORV use from October 15 through March 14, and approximately 13 miles would be designated as vehicle free year-round. The speed limit would be 15 mph unless otherwise posted, and permits would be required for all ORVs. Three SMAs that are seasonally

designated as vehicle free from March 15 to October 14 would be managed under ML2 procedures and would maintain an open pedestrian access corridor along the shoreline to the inlet or point, subject to resource closures.

The seasonal restriction on ORVs and pedestrians in SMAs, the level of monitoring provided, and the size of the buffers under alternative C would reduce the potential of disturbance and nest abandonment from direct short-term contact with people and/or essential vehicles compared to alternatives A and B. In addition, the preclusion of ORV access in the SMAs for the entire breeding season would reduce the level of recreational use in sensitive resource areas. Although these measures should limit adverse impacts to piping plover, compliance with closures may not be absolute, since alternative C still includes pedestrian access to Bodie Island Spit, Cape Point, and South Point during the breeding season, and the areas closed are not expansive or contiguous. Therefore, recreational uses could result in short-term moderate adverse impacts if non-compliance occurs.

Establishment of SMAs and prescribed buffers and exclusion of ORVs from these areas during the breeding season would reduce pressure on the species from recreational uses at the Seashore. Under this alternative, recreational activities would still occur in the vicinity of the species and would still have the potential to impact them, with minor to moderate adverse impacts to piping plover from recreational use, and minor to moderate benefits from the protection offered.

*Night-Driving Restrictions.* Under alternative C, operation of all nonessential ORV traffic would be prohibited from all areas (other than the soundside) between 7:00 p.m. and 7:00 a.m. from May 1 to November 15. From November 16 to April 30, ORV use would be allowed 24 hours per day in designated ORV routes for vehicles holding valid ORV permits. Furthermore, NPS retains the discretion to limit night driving to certain areas or routes, based on resource protection considerations. Because plovers are known to be active at night (Staine and Burger 1994; Majka and Shaffer 2008), and plover chick and fledgling response to vehicles can increase their vulnerability to ORVs (USFWS 1996a, 2009a), the high level of protection at night from May 1 to November 15 under alternative C would result in long-term moderate beneficial impacts because it would reduce the potential for disturbance to plovers that could result in mortality.

*Commercial Fishing.* Commercial fishing vehicle access would be the same as under alternative A and would be managed by the terms and conditions in the commercial fishing special use permit, which includes restriction from entering resource closures. Commercial fisherman would not be required to obtain an ORV permit, but would be regulated under their existing use permit. Under alternative C, commercial fishing vehicles would be authorized to enter VFAs, but would not be allowed to enter resource closures or lifeguarded beaches. Night-driving restrictions, which are applicable to all ORV use, could be modified by up to +/- 2 hours for commercial fishing purposes. Presence of commercial fishing operations would have a long-term negligible adverse impact, with long-term minor to moderate benefits from night-driving restrictions.

*Permit/Carrying Capacity.* As described above under the night-driving restrictions and education/outreach sections, alternative C would require a permit for ORV use, including night driving. As stated in these sections, as a result of the educational information provided by the permit, there would be long-term minor to moderate benefits to piping plover as ORV users would be more aware of the regulations in place to protect this species, which would likely result in a higher level of compliance with buffer, closures, and other restrictions. ORV carrying capacity established under alternative C would not directly impact piping plover, as ORV use would not be allowed in resource protection areas.

*Pets/Other Recreational Activity Restrictions.* Pets would be prohibited within all SMAs from March 15 to October 14 and within all nonbreeding shorebird SMAs that are otherwise open to recreational use;

however, compliance would be needed to ensure that this reduces the risks of impacts. In addition, an educational permit would be required for any beach fire year-round, which would inform visitors about species protection issues related to this recreational activity. Camping restrictions would be the same as those under alternative A, with additional requirements for removing unattended beach equipment prior to nightfall. These restrictions would result in long-term minor to moderate benefits to species at the Seashore, further reducing pressure to piping plover from recreational activity.

*Overall Impacts from ORV and Other Recreational Use.* Overall, impacts to piping plover from ORV and other recreational use would be long-term minor adverse. The establishment of the SMAs, which proactively reduce or preclude recreational use early in the breeding season; ORV permit requirements; seasonal night-driving restrictions; and pet and other recreational activity restrictions would all provide benefits in terms of species protection. As there would still be some opportunity for recreational use to come in contact with and impact piping plovers, and the fact that alternative C would still include some level of pedestrian access to three SMAs during a portion of the breeding season, impacts to piping plover would be long-term minor adverse.

**Cumulative Impacts.** The same past, present, and future actions discussed under the cumulative impact scenario for alternative A would occur under alternative C. The overall cumulative impact of these past, current, and future actions would be long-term negligible to minor, depending on the intensity and duration of unpredictable factors such as storm events, with long-term moderate beneficial impacts from actions such as increased interpretive programs as part of the long-range interpretive plan and predator management within the Seashore. Many of these actions do not directly impact piping plover habitat in the area, as most of this habitat is located within the Seashore and is affected by NPS management actions more than any of the aforementioned past, present, and future actions. These impacts, combined with the long-term minor adverse, as well as minor to moderate beneficial impacts of alternative C, would be long-term minor adverse impacts, as actions within the Seashore would act as a driver for overall cumulative impact.

**Conclusion.** Overall impacts under alternative C from resources management activities would be long-term moderate beneficial. As with alternative B, minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of prenesting closures within the SMAs early in the breeding season, monitoring activities, and establishment of prescribed buffers would provide long-term moderate beneficial impacts to the species. Overall impacts under alternative C from ORV and other recreational use would be long-term minor adverse. The establishment of the SMAs, which proactively reduce or preclude recreational use early in the breeding season; prohibition of ORV use in SMAs between March 15 and October 14; ORV permit requirements; seasonal night-driving restrictions; and restrictions on pets and other recreational activities would all provide benefits in terms of species protection. As there would still be some opportunity for recreational use to come in contact with and impact the species, impacts to piping plovers would be long-term minor adverse.

Cumulative impacts under alternative C would be long-term minor adverse.

**Determination of Effect.** Under the ESA, the actions taken under alternative C may affect / are likely to adversely affect piping plover due to the minor adverse effects from monitoring and surveying and the minor adverse effects of ORV and other recreational use. Establishment of these SMAs and prenesting closures early in the breeding season would have long-term moderate benefits to piping plover. ORV use and pedestrian access would result in long-term minor adverse impacts as the SMAs and larger buffers would reduce pressure from recreational uses on piping plovers. However, recreational uses would still occur in the vicinity of plovers during breeding season. Restricting ORV use at night from May 1 to November 15 would offer a higher level of protection than alternatives A and B and would have long-term moderate benefits to foraging plovers. These impacts would result in a finding of may affect / are

likely to adversely affect piping plovers under the ESA because the action would result in direct or indirect impacts to the species that are not discountable, insignificant, or beneficial. And while there may be beneficial impacts from monitoring, surveying, and management of recreation, the actions under alternative C would also likely result in some adverse effects.

Under the ESA, the actions taken under alternative C may affect / are not likely to adversely affect designated critical habitat for wintering piping plover due to the establishment of SMAs which would result in the closure of approximately 13 miles of shoreline to ORV use year round, which would provide relatively less-disturbed foraging, resting, and roosting areas for migrating and wintering shorebirds. These closures would protect the primary constituent elements of intertidal sand beaches and backshores in these areas. Year-round VFAs along the ocean shoreline would be managed as Nonbreeding Shorebird SMAs with recreational activity restrictions, such that if staff determines that any single recreational activity or collection of activities is negatively impacting nonbreeding piping plover use of a specific location, NPS may implement additional restrictions on activities. Nonbreeding Shorebird SMAs would also be established at the points and spits based on an annual habitat assessment, which would provide protection for interior wintering plover habitat. There would be some benefit to the critical habitat from the implementation of seasonal night-driving restrictions although these restrictions would only apply between May 1 and November 15, which would not cover the majority of time when the wintering population of piping plover is present at the Seashore.

Although there would be construction of ORV access ramps, parking areas, and interdunal roads, none of these improvements would impact any of the primary constituent elements of designated critical habitat for wintering piping plover.

Implementation of alternative C would result in a finding of may affect / is not likely to adversely affect designated critical habitat for wintering piping plover under the ESA because the action would result in impacts to the critical habitat for the species that are discountable, insignificant, or beneficial. Actions under alternative C would result in greater protection of the primary constituent elements of suitable interior habitat, spits, intertidal sand beaches, and ocean backshore, primarily as a result of the establishment of Nonbreeding Shorebird SMAs and approximately 13 miles of year-round VFAs.

## **Impacts of Alternative D: Increased Predictability and Simplified Management**

### **Resources Management Activities**

*Establishment of Prenesting Closures.* Prenesting surveying activities for piping plovers under alternative D would be carried out as described under alternative C, which would include the survey and evaluation of all potential breeding habitats by Seashore staff by March 1 of each year with piping plover prenesting closures recommendations based on that evaluation. Under alternative D, all designated breeding SMAs would be posted as prenesting closures using symbolic fencing by March 15 of each year. All SMAs under alternative D would be managed under ML1 procedures, which would prohibit recreational access while the closures are in place, and would provide long-term major benefits to the species.

*Surveying and Monitoring.* Surveys and monitoring during prenesting, nesting, and chick rearing life stages would be largely similar to alternative C. However, under alternative D, ML1 procedures would be implemented in all SMAs during the breeding season, resulting in a reduction in the frequency of monitoring required compared to alternatives that either do not designate any SMAs or those that employ ML2 procedures and therefore require more frequent monitoring. Under the ML1 procedures in alternative D, all SMAs containing piping plover habitat would be closed to public access throughout the breeding season.

Because the frequency of monitoring would be reduced under alternative D, the impacts from surveying and monitoring, such as disturbance to piping plover at various life stages would also be reduced. Monitoring and surveying would result in minor to moderate, beneficial impacts to piping plover by providing Seashore managers with information on habitats used by breeding and nonbreeding piping plovers and the locations of those habitats, as well as potential threats they may contain. Surveying and monitoring would increase knowledge on how and when piping plover use the Seashore and thereby enabling the NPS to implement adaptive management initiatives, providing a beneficial impact. However, as with all the alternatives, surveying and monitoring would bring people and/or essential vehicles into direct short-term contact with piping plovers and their habitat, and these activities themselves are known risk factors, especially during the more sensitive life stages of early prenesting and territory establishment. Under alternative D, many precautions would be taken by staff to minimize impacts from monitoring such as using high powered scopes and thereby reducing impacts from intrusion by monitors. The impact of the monitoring when these precautions are taken into consideration would be minor. Although there would be adverse impacts such as disturbance to piping plover at various life stages, the protection that would result from surveying would result in long-term moderate beneficial impacts.

*Buffer/Closure Establishment.* Under alternative D, ML1 procedures would be implemented during the breeding season at all SMAs including Bodie Island Spit, Cape Point, and South Point, which would preclude all public access throughout the breeding season and all ORV use year-round. ML1 procedures measures designate 75-meter buffers around any piping plover nests and scrapes. ML1 procedures provide 1,000-meter buffers for both ORVs and pedestrians around unfledged chicks, as opposed to ML2 procedures in other action alternatives that reduce this to 300-meters for pedestrians. Because buffers under ML1 procedures are larger, there would be less monitoring required resulting in fewer changes in closure fencing by Seashore staff. Piping plovers would likely experience long-term moderate to major benefits from the size and duration of the closures and from the fact that buffers would adjust in response to chick mobility under ML1 procedures.

In addition to the closure of all SMAs to public access during the breeding season, alternative D provides for the protection of piping plover nests through the use of buffer distances recommended, in part, under the Piping Plover Recovery Plan (USFWS 1996a) as described under alternative C. If piping plover breeding activity occurs outside of the SMAs, adverse impacts could result if implementation of or adjustments to a buffer are not made in a timely manner. This outcome may be more likely under the reduced monitoring associated with alternative D and ML1 procedures, or if nests or acts of deliberate disturbance are not detected by Seashore staff.

Under alternative D designated SMAs would be subject to periodic review, as described under alternative C, resulting in long-term moderate beneficial impacts. Overall, the benefit of the preclusion of all public access in SMAs during the breeding season would outweigh the disturbance inherent with species management, and result in long-term moderate to major beneficial impacts from species closures and buffers.

*Management of Wintering/Nonbreeding Populations.* Management of wintering/nonbreeding populations under alternative D would be the same as those under alternative C, resulting in long-term moderate beneficial impacts.

*Education and Outreach.* Under alternative D, impacts as a result of education and outreach, including education from a permit system, would be the same as those under alternative C and would result in long-term minor to moderate beneficial impacts.

*Overall Impacts of Resources Management Activities.* Overall impacts to piping plover from resources management activities (primarily resulting from the effects of surveying and field activities) under

alternative D would be long-term moderate to major beneficial. As with all species management activities, minor adverse impacts would occur from human presence during monitoring, but on the whole the implementation of SMAs that prohibit ORV use year-round and only allow pedestrian access outside of the breeding season, establishment of prenesting closures early in the breeding season, monitoring activities, and establishment of prescribed buffers would provide long-term moderate to major beneficial impacts to the species.

### **ORV and Other Recreational Use**

*ORV and Pedestrian Access.* Alternative D is designed to provide visitors to the Seashore with the maximum amount of predictability regarding routes available for ORV use and VFAs for pedestrian use, which means establishing year-round ORV route and VFA designations. Under this alternative, year-round VFAs would include the area in front of villages and lifeguarded beaches, as well as all SMAs, which include the points and spits. Approximately 27 miles of shoreline would be designated for ORV use and approximately 40 miles would be designated as vehicle free year-round. VFAs would be open to pedestrian access, except for the SMAs during breeding season and potentially other locations outside the SMAs if breeding activity occurs. There would be no seasonally designated ORV routes. In designated ORV areas, the speed limit would be 15 mph unless otherwise posted, and permits would be required for all ORVs. Other uses would still be allowed in these VFAs outside of any identified resource closures/SMAs. As noted in chapter 3, a 3-year study on Cape Cod and Fire Island, New York (Kluft and Ginsberg 2009), found that higher ORV traffic resulted in dispersal and desiccation of the wrack line, thereby reducing the population of invertebrates in that area. Alternative D would allow for beach driving in the wrack on ORV routes during the day, but would maintain nighttime closures and daytime closures where SMAs are established reducing disturbance in these areas. Compared to other alternatives, this alternative would also limit daytime ORV use in more areas of the Seashore. Overall impact to invertebrates would be long-term and negligible (as discussed later in this chapter), and would reduce the food source available to birds at the Seashore, but to a lesser degree than if night driving or greater access during the day was permitted, resulting in long-term negligible impacts.

Restricted access within large contiguous areas, including all points and spits, under alternative D would provide long-term moderate to major beneficial impacts to the piping plover (as described above under buffer/closure establishment), with greater benefits associated with fewer occurrences of non-compliance that would be expected from restrictions that would essentially eliminate a conduit or access way for ORVs and pedestrians in these sensitive areas. Disturbance from direct short-term contact with people and/or ORVs should be greatly reduced compared to alternatives A, B, and C, because of the amount of Seashore that is designated as vehicle free year-round, including all points and spits, which are the primary breeding and foraging areas for piping plover. Closures to pedestrians in all SMAs during the breeding season would also reduce the potential for disturbance to breeding plovers. As with all alternatives, compliance with closures would be an enforcement issue for the NPS, although with the size/length of the VFAs, non-compliance would be much less likely. It is recognized that compliance would still be less than absolute, with a potential for short-term adverse impacts, but overall alternative D would provide substantial benefits to the species. Adverse impacts from ORV and pedestrian access would be expected to be long-term minor adverse.

*Night-Driving Restrictions.* Under alternative D, night-driving restrictions would be the same as under alternative C and would result in long-term moderate beneficial impacts as it would further reduce the potential for disturbance to night-foraging plover that could result in mortality, although foraging of piping plover outside of the SMAs is unlikely.

*Commercial Fishing.* Commercial fishing activities under alternative D would be the same as alternative C and would result in long-term negligible adverse impacts, with long-term minor to moderate benefits from night-driving restrictions.

*Permit/Carrying Capacity Requirements.* As described above under the night-driving restrictions and education/outreach sections, alternative D would require a permit for ORV use, including night driving. As stated in these sections, as a result of the educational information provided by the permit, there would be long-term minor to moderate benefits to piping plover as ORV users would be more aware of the regulations in place to protect these species, which would likely result in a higher level of compliance with buffer, closures, and other restrictions. There would be no impacts related to carrying capacity, as it would not be a requirement under alternative D, other than one-deep vehicle stacking restrictions.

*Pets/Other Recreational Activity Restrictions.* Pets would be prohibited within all SMAs year-round. Camping would not be permitted at the Seashore, and beach fires would be regulated with a non-fee educational permit, as described under alternative C. Prohibition of pets within the SMAs year-round and additional education from a beach fire permit would be expected to have long-term minor to moderate beneficial impacts to the species, greater than those under alternative C, provided the level of non-compliance is kept low.

*Overall Impacts from ORV and Other Recreational Use.* Overall impacts under alternative D from ORV and other recreational use would be long-term minor adverse. The establishment of SMAs that are closed to ORVs year-round and managed under ML1 procedures during the breeding season would proactively preclude recreational use early in the breeding season from large areas of the Seashore, which would reduce the potential for disturbance to plovers during critical life stages. This protection, combined with ORV permit requirements, seasonal night-driving restrictions, and pet and other recreational activities restrictions would all provide benefits in terms of species protection. As there would still be some opportunity for recreational use to come in contact with and impact the species, impacts would be long-term minor adverse.

**Cumulative Impacts.** The same past, present, and future actions discussed under the cumulative impact scenario for alternative A would occur under alternative D. The overall cumulative impact of these past, current, and future actions, would be long-term negligible to minor, depending on the intensity and duration of unpredictable factors such as storm events, with long-term moderate beneficial impacts from actions such as increased interpretive programs as part of the long-range interpretive plan and predator management within the Seashore. Many of these actions do not directly impact piping plover habitat in the area, as most of this habitat is located within the Seashore and is impacted by NPS management actions more than any of the aforementioned past, present, and future actions. These impacts, combined with the long-term minor adverse, as well as minor to major beneficial impacts of alternative D, would be long-term minor adverse impacts, as actions within the Seashore would act as a driver for overall cumulative impacts.

**Conclusion.** Overall impacts to piping plover from resources management activities (primarily resulting from the effects of surveying and field activities) under alternative D would be long-term moderate to major beneficial. As with all species management activities, minor adverse impacts would occur from human presence during monitoring, but on the whole the implementation of SMAs that prohibit ORV use year-round and only allow pedestrian access outside of the breeding season, establishment of prenesting closures early in the breeding season, monitoring activities, and establishment of prescribed buffers would provide long-term moderate to major beneficial impacts to the species. Overall impacts under alternative D from ORV and other recreational use would be long-term minor adverse. The establishment of SMAs that are closed to ORVs year-round and managed under ML1 procedures during the breeding season would proactively preclude recreational use early in the breeding season from large areas of the Seashore,

which would reduce the potential for disturbance to plovers during critical life states. This protection, combined with ORV permit requirements, seasonal night-driving restrictions, and pet and other recreational activities restrictions would all provide benefits in terms of species protection. As there would still be some opportunity for recreational use to come in contact with and impact the species, impacts would be long-term minor adverse.

Cumulative impacts would be long-term minor adverse.

**Determination of Effect.** Under the ESA, the actions taken under alternative D may affect / are likely to adversely affect piping plover due to the minor adverse effects from monitoring and surveying and the minor adverse impacts from ORV and other recreational use. Establishment of SMAs with year-round ORV closures and prenesting closures early in the breeding season would have long-term moderate to major benefits to piping plover. ORV use and pedestrian access would result in long-term minor adverse impacts as the SMAs and larger buffers would reduce pressure from recreational uses on plovers. However, recreational uses would still occur in the vicinity of plovers during breeding season. Restricting ORV use at night from May 1 to November 15 would offer a higher level of protection than alternatives A and B and would have long-term moderate benefits to foraging plovers. These impacts would result in a finding of may affect/ are likely to adversely affect piping plovers under ESA because the action would result in direct or indirect impacts to the species that are not discountable, insignificant, or beneficial. And while there may be beneficial impacts from monitoring, surveying, and management of recreation, the actions under alternative D would also likely cause some adverse effects.

Under the ESA, the actions taken under alternative D may affect / are not likely to adversely affect designated critical habitat for wintering piping plover due to the establishment of SMAs which would result in the closure of approximately 40 miles of shoreline to ORV use year round, including ocean beaches along all of the points and spits. These closures would provide less-disturbed foraging, resting, and roosting areas for migrating and wintering shorebirds and would protect the primary constituent elements of intertidal sand beaches, backshores, and spits. These year-round VFAs along the ocean shoreline would be managed as Nonbreeding Shorebird SMAs with recreational activity restrictions, such that if staff determines that any single recreational activity or collection of activities is negatively impacting nonbreeding piping plover use of a specific location, NPS may implement additional restrictions on activities. Nonbreeding Shorebird SMAs would also be established at the points and spits based on an annual habitat assessment, which would provide protection for interior wintering plover habitat. There would be some benefit to the critical habitat from the implementation of seasonal night-driving restrictions although these restrictions would only apply between May 1 and November 15, which would not cover the majority of time when the wintering population of piping plover is present at the Seashore.

Although there would be construction of ORV access ramps, parking areas, and interdunal roads, none of these improvements would impact any of the primary constituent elements of designated critical habitat for wintering piping plover.

Implementation of alternative D would result in a finding of may affect / is not likely to adversely affect designated critical habitat for wintering piping plover under the ESA because the action would result in impacts to the critical habitat for the species that are discountable, insignificant, or beneficial. Actions under alternative D would result in greater protection of the primary constituent elements of suitable interior habitat, spits, intertidal sand beaches, and ocean backshore, primarily as a result of the establishment of Nonbreeding Shorebird SMAs and 40 miles of year-round VFAs.

## Impacts of Alternative E: Variable Access and Maximum Management

### Resources Management Activities

*Establishment of Prenesting Closures.* Prenesting surveying activities for piping plovers under alternative E would be carried out as described under alternative C, which would include the survey and evaluation of all potential breeding habitats by Seashore staff by March 1 of each year with piping plover prenesting closures recommendations based on that evaluation. Under alternative E, all designated breeding SMAs would be posted as prenesting closures using symbolic fencing by March 15 of each year. However, under alternative E, Bodie Island Spit, Cape Point, and South Point would be managed under ML2 procedures, which would include the establishment of an ORV pass-through zone at the start of the breeding season, which would be subject to resource closures if necessary. Establishment of these SMAs and prenesting closures early in the breeding season would have long-term moderate benefits to piping plover.

*Surveying and Monitoring.* Surveys and monitoring during prenesting, nesting, and chick rearing life stages would be the same as alternative C. Protected species buffers would follow ML1 procedures at most areas of the Seashore, with the exception of Bodie Island Spit, Cape Point, and South Point, where ML2 procedures would apply. Because surveying and monitoring protocols would be the same as alternative C, these protocols would result in long-term moderate beneficial impacts to piping plovers by providing Seashore managers with information on the types and location of habitats used by nonbreeding piping plovers, seasonality of plover use of the Seashore, tidal influences on habitat use, and potential threats the habitat may contain. Surveying would increase knowledge on how and when piping plovers use the Seashore and enable adaptive management initiatives and contribute to better management.

As with all the alternatives, surveying and monitoring would bring people and/or essential vehicles into direct short-term contact with piping plovers and their habitat, and these activities themselves are known risk factors, especially during the more sensitive life stages of early prenesting and territory establishment. Under alternative E, like alternative C, many precautions would be taken by staff to minimize impacts from monitoring, such as using high powered scopes, thereby reducing impacts from intrusion by monitors. The impact of the monitoring when these precautions are considered would be minor. Although there would be adverse impacts such as disturbance to piping plover at various life stages, the protection that would result from surveying would result in long-term moderate beneficial impacts.

*Buffer Closure/Establishment.* Under alternative E, SMAs would be established and the level of species management designated either ML1 or ML2. ML1 procedures would not allow ORV or pedestrian access when prenesting closures are in effect. Bodie Island Spit, Cape Point, and South Point would be managed under ML2 procedures and would include a narrow ORV access corridor at the start of the breeding season that would be subject to resource closures if necessary. ML1 procedures require 75-meter buffers around any piping plover nests or scrapes. ML1 procedures provide 1,000-meter buffers for both ORVs and pedestrians around unfledged chicks, as opposed to ML2 procedures, which reduce this distance to 300 meters for pedestrians. Because buffers under ML1 procedures are larger, there would be less monitoring required, resulting in fewer changes in closure fencing by Seashore staff. Piping plovers would likely experience moderate long-term benefits from the size and duration of the closures and from the fact that buffers would adjust in response to chick mobility.

Like alternative C, in addition to prenesting areas and the general reduction in recreational pressure provided by the SMAs, alternative E would provide for protection of piping plover nests outside of the SMAs through the use of buffer distances described under alternative C. Although the species would be offered protection by these buffers, short-term adverse impacts could result to piping plover if

adjustments to a buffer are not made in a timely manner or if nests or acts of deliberate disturbance are missed by Seashore staff outside of the SMAs areas. Therefore, the buffers under alternative E would be expected to have long-term moderate beneficial effects on the species because the benefits outweigh the adverse effects of surveys and monitoring. Alternative E would also include periodic review (as described under alternative C), which would provide additional benefits to the species, as management actions could be altered to provide improved protection for plovers.

*Management of Wintering/Nonbreeding Populations.* Under alternative E, as described under alternatives C and D, SMAs would be established for migrating/wintering shorebirds at various locations throughout the Seashore. Closures would be established no later than when breeding season closures are removed at the same location(s), resulting in long-term moderate beneficial impacts from this protection.

Nonbreeding resource closures would be established at the spits and Cape Point based on habitat used by wintering piping plovers in more than one of the past five years, the presence of birds at the beginning of the migratory season, and suitable habitat types based on the results of the annual habitat assessment. In addition to nonbreeding resource closures, designated VFAs along the ocean shoreline would provide areas of reduced ORV disturbance for foraging, resting, and roosting areas for migrating and wintering shorebirds.

*Education and Outreach.* Under alternative E, impacts as a result of education and outreach, including education from a permit system, would be the same as those under alternative C and would result in long-term minor to moderate beneficial impacts to piping plover.

*Overall Impacts of Resources Management Activities.* Overall impacts under alternative E from resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term moderate beneficial. As with all species management activities, minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of SMAs early in the breeding season, monitoring activities, and establishment of prescribed buffers would provide long-term moderate beneficial impacts to the species.

### **ORV and Other Recreational Use**

*ORV and Pedestrian Access.* Under alternative E, approximately 32 miles of shoreline would be designated for ORV use year-round, approximately 20 miles would be designated for seasonal ORV use from September 1 through March 14, and approximately 16 miles would be designated as vehicle free year-round. The speed limit would be 15 mph unless otherwise posted, and permits would be required for all ORVs. In the SMAs, under ML2 procedures, adjacent to the prenesting area, NPS would provide an ORV corridor with a pass-through zone at the start of the breeding season (March 15). When breeding activity is observed, standard buffers would apply, which depending upon the circumstances could close the access corridor until breeding activity has concluded. As noted in chapter 3, a 3-year study on Cape Cod and Fire Island, New York (Kluft and Ginsberg 2009), found that higher ORV traffic resulted in dispersal and desiccation of the wrack line, thereby reducing the population of invertebrates in that area. Alternative E would allow for beach driving in the wrack on ORV routes during the day outside of SMAs, but would maintain nighttime closures and limit driving during the day where SMAs are established reducing disturbance in these areas. Overall impacts to invertebrates would be long-term and minor (as discussed later in this chapter), and would reduce the food source available to birds at the Seashore, but to a lesser degree than if night driving was permitted, resulting in long-term minor impacts.

The designation of SMAs and other restrictions under alternative E would reduce the potential of disturbance and nest abandonment from direct short-term contact with people and/or essential vehicles compared to alternatives A and B, but would have greater impacts than alternative C due to the existence

of an ORV pass-through at three SMAs, which would create a conduit to the points and spits for ORVs. Alternative E would also reduce the duration of ORV closures in SMAs managed under ML1 procedures by allowing ORV use starting September 1 instead of October 14 (alternative C). Impacts would also be greater under alternative E than alternative D, which has all SMAs closed to ORV and pedestrian use during the breeding season. Although these measures should limit adverse impacts to piping plover, compliance with closures may not be absolute, since alternative E still includes access to some points and spits, which could result in short-term moderate adverse impacts if non-compliance occurs.

Although the SMAs would be beneficial to the species, continued recreational use in this area would still result in potential long-term minor to moderate adverse impacts to the species, which would be greater than those impacts under alternative C because of the increased level of access provided under alternative E and the shorter duration of SMA closures.

*Night-Driving Restrictions.* Under alternative E, night-driving restrictions would be similar to those in alternative B and would result in long-term minor to moderate beneficial impacts because it would reduce the potential for disturbance to night-foraging birds that could result in mortality. However, ORV use would still be allowed until 10:00 p.m. from May 1 through November 15, which would result in ORVs on the beach after dark and could still result in some level of adverse impact.

*Commercial Fishing.* Management of commercial fishing under alternative E would be the same as alternative C resulting in long-term negligible adverse impacts from the presence of commercial fishing vehicles, with long-term minor to moderate benefits from night-driving restrictions.

*Permit/Carrying Capacity.* As described above under the night-driving restrictions and education/outreach sections, alternative E would require a permit for ORV use, including night-driving. As stated in these sections, as a result of the educational information provided by the permit, there would be long-term minor to moderate benefits to piping plover as ORV users would be more aware of the regulations in place to protect these species, which would likely result in a higher level of compliance with buffer, closures, and other restrictions. There would be no impacts to piping plover related to carrying capacity, for reasons described under alternative C.

*Pets/Other Recreational Activity Restrictions.* Pets would be prohibited within all SMAs from March 15 to August 31. As with alternative C, an educational permit would be required for any beach fire year-round, which would inform visitors about species protection issues related to this recreational activity.

Camping restrictions would be the same as alternative C; however, park-and-stay permits for overnight beach use would be issued at selected spits and points that are not closed for resource protection. The provision for park-and-stay overnight at some spits and points during portions of the breeding season when resource closures do not preclude access would increase the potential for human disturbance to nesting birds adjacent to those locations.

Pet, camping, and beach fire restrictions would result in long-term minor to moderate benefits to species at the Seashore, further reducing pressure to piping plover from recreational activity, with the potential for long-term minor to moderate adverse impacts from the park-and-stay option, which would occur outside of resource closures.

*Overall Impacts from ORV and Other Recreational Use.* Overall impacts under alternative E from ORV and other recreational use would be long-term minor to moderate adverse. The establishment of the SMAs which proactively reduce or preclude recreational use early in the breeding season, ORV permit requirements, and pet and other recreational activity restrictions would all provide benefits in terms of species protection. Although there would be benefits from seasonal night-driving restrictions, they would

not be as great as other action alternatives because driving after dark (until 10:00 p.m.) would still be occurring, even during seasonal restrictions. The potential for adverse impacts would exist from the park-and-stay option under this alternative. As there would still be some opportunity for recreational use to come in contact with and impact the species, impacts would be long-term minor to moderate adverse.

**Cumulative Impacts.** The same past, present, and future actions discussed under the cumulative impact scenario for alternative A would occur under alternative E. The overall cumulative impact of these past, current, and future actions, would be long-term negligible to minor, depending on the intensity and duration of unpredictable factors such as storm events, with long-term moderate beneficial impacts from actions such as increased interpretive programs as part of the long-range interpretive plan and predator management within the Seashore. Many of these actions do not directly impact piping plover habitat in the area, as most of this habitat is located within the Seashore and is impacted by NPS management actions more than any of the aforementioned past, present, and future actions. These impacts, combined with the long-term minor to moderate adverse, as well as minor to moderate beneficial impacts of alternative E, would be long-term minor to moderate adverse impacts, as actions within the Seashore would act as a driver for overall cumulative impact.

**Conclusion.** Overall impacts under alternative E from resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term moderate beneficial. As with all species management activities, minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of SMAs early in the breeding season, monitoring activities, and establishment of prescribed buffers would provide long-term moderate beneficial impacts to the species.

Overall impacts under alternative E from ORV and other recreational use would be long-term minor to moderate adverse. The establishment of the SMAs which proactively reduce or preclude recreational use early in the breeding season, ORV permit requirements, and pet and other recreational activity restrictions would all provide benefits in terms of species protection. Although there would be benefits from seasonal night-driving restrictions, they would not be as great as other action alternatives because driving after dark (until 10:00 p.m.) would still be occurring, even during seasonal restrictions. The potential for adverse impacts would exist from the park-and-stay option under this alternative. As there would still be some opportunity for recreational use to come in contact with and impact the species, impacts would be long-term minor to moderate adverse.

Cumulative impacts under alternative E would be long-term minor to moderate adverse.

**Determination of Effect.** Under the ESA, the actions taken under alternative E may affect / are likely to adversely affect piping plover due to the minor adverse effects from monitoring and surveying and the minor to moderate adverse effects from ORV and pedestrian access. Areas managed under ML2 procedures would accommodate a narrow ORV access corridor at the start of the breeding season. However, under alternative E, most SMAs would be closed to ORV use from March 15 through August 31, except Bodie Island Spit, Cape Point, and South Point which would include an ORV pass-through zone, subject to resource closures. Establishment of these SMAs and prenesting closures early in the breeding season would have long-term moderate benefits to piping plover. However, recreational uses would still occur in the vicinity of plovers during breeding season. All recreational ORV traffic would be prohibited from 10:00 p.m. until 6:00 a.m. from May 1 to September 15. From September 16 to November 15, night-driving permits would be available for authorized nonessential driving between the hours of 10:00 p.m. and 6:00 a.m. These restrictions to night driving would provide long-term minor to moderate benefits to piping plovers but could still result in long-term minor adverse impacts during the time when night driving is allowed by permit. These impacts would result in a finding of may affect/ are likely to adversely affect piping plovers under ESA because the action would result in direct or indirect

impacts to the species that are not discountable, insignificant, or beneficial. And while there may be beneficial impacts from monitoring, surveying, and management of recreation, the actions under alternative E would also likely cause some adverse effects.

Under the ESA, the actions taken under alternative E may affect / are not likely to adversely affect designated critical habitat for wintering piping plover due to the establishment of SMAs which would result in the closure of approximately 16 miles of shoreline to ORV use year round. These closures would provide less-disturbed foraging, resting, and roosting areas for migrating and wintering shorebirds and would protect the primary constituent elements of intertidal sand beaches and ocean backshores. These year-round VFAs along the ocean shoreline would be managed as Nonbreeding Shorebird SMAs with recreational activity restrictions, such that if staff determines that any single recreational activity or collection of activities is negatively impacting nonbreeding piping plover use of a specific location, NPS may implement additional restrictions on activities. Nonbreeding Shorebird SMAs would also be established at the points and spits based on an annual habitat assessment, which would provide protection for interior wintering plover habitat. There would be some benefit to the critical habitat from the implementation of seasonal night-driving restrictions although these restrictions would only apply between May 1 and November 15, which would not cover the majority of time when the wintering population of piping plover is present at the Seashore.

Although there would be construction of ORV access ramps, parking areas, and interdunal roads, none of these improvements would impact any of the primary constituent elements of designated critical habitat for wintering piping plover.

Implementation of alternative E would result in a finding of may affect / is not likely to adversely affect designated critical habitat for wintering piping plover under the ESA because the action would result in impacts to the critical habitat for the species that are discountable, insignificant, or beneficial. Actions under alternative E would result in greater protection of the primary constituent elements of suitable interior habitat, spits, intertidal sand beaches, and ocean backshore, primarily as a result of the establishment of Nonbreeding Shorebird SMAs and approximately 16 miles of year-round VFAs.

## **Impacts of Alternative F: NPS Preferred Alternative**

### **Resources Management Activities**

*Establishment of Prenesting Closures.* Prenesting surveying activities for piping plovers under alternative F would be carried out as described under alternative C, which would include the survey and evaluation of all potential breeding habitats by Seashore staff by March 1 of each year with piping plover prenesting closures recommendations based on that evaluation. Under alternative F, areas of suitable habitat that have had individual piping plover nests in more than one of the past five years and new habitat that is particularly suitable for nesting (such as the habitat at new inlets or overwash areas) would be posted as prenesting closures using symbolic fencing by March 15 of each year. Establishment of these prenesting closures early in the breeding season would have long-term moderate benefits to piping plover.

*Surveying and Monitoring.* Surveys and monitoring during prenesting, nesting, and chick-rearing life stages would be similar to alternatives C and E, except surveys of scrapes/nests would be modified to allow monitoring to occur from a distance if the observations would result in disturbance to other nesting species in the area. Surveying and monitoring during all life stages, as described under alternatives C and E, would bring people and/or essential vehicles into direct short-term contact with piping plovers and their habitat, and these activities themselves are known risk factors, especially during the more sensitive life stages of early prenesting and territory establishment. However, many precautions would be taken by staff to minimize impacts, for example, using scopes to watch the birds from a distance, and remaining

outside closures to the extent possible. Overall, pre-breeding surveying, post-breeding monitoring, and management actions proposed under alternative F would have a long-term moderate beneficial impact, providing the Seashore with additional data and information that would enable the implementation of adaptive management initiatives and contribute to better management.

*Buffer/Closure Establishment.* Prenesting closures would be established by March 15, as described above. ORV corridors would be provided at Cape Point and South Point seaward of the prenesting closure, with the corridor being reduced from 50 meters (164 feet) to 35 meters (115 feet) during the breeding season. Allowing an ORV corridor would allow more access in prenesting closures than under alternatives C, D, and E, as SMAs would not allow for access in these areas. As with alternative C, these prenesting closures would be removed by July 31 if no birds are present, or two weeks after all chicks have fledged, whichever comes later. Alternative F also provides for seasonal ORV closures of Bodie Island Spit and of the new interdunal road from the eastern portion of Spur Road west toward the inlet on Hatteras Island, which would provide protection from ORV use to piping plovers nesting in those areas, although pedestrian use would still be permitted. Several areas that are designated as SMAs under alternatives C, D, and E would be designated as VFAs under alternative F including the following segments of the Seashore:

- Ramp 1 to 0.5 miles south of Coquina Beach (year-round)
- 0.2 mile south of ramp 4 to southeast corner of Bodie Island spit (vehicle free March 15 to September 14)
- Southeast corner of Bodie Island spit along inlet shoreline to southwest edge of Bait Pond (near bridge) (year-round)
- Rodanthe boundary to 0.1 mile south of Rodanthe pier (year-round)
- 0.1 mile south of Rodanthe Pier–Waves–Salvo to ramp 23 (vehicle free April 1 to October 31)
- Ramp 23 to 1.5 miles south of ramp 23 (year-round)
- Ramp 27 to ramp 30 (year-round)
- Ramp 32.5 to ramp 34 (year-round)
- Ramp 34 to ramp 38 (vehicle free April 1 to October 31)
- Ramp 38 to 1.5 miles south of ramp 38 (i.e., Haulover) (year-round)
- 0.3 mile west of the hook (Cape Point) to 1.7 miles west of ramp 45 (year-round)
- Frisco Village Beach (east village boundary to west boundary) (vehicle free April 1 to October 31)
- Sandy Bay / Frisco day use area (west Frisco boundary to east Hatteras Village boundary) (year-round)
- Hatteras Village Beach (east boundary to ramp 55) (vehicle free April 1 to October 31)
- Bone Road to Hatteras Inlet, along inlet shoreline to Spur Road (year-round)
- (New) interdunal road from eastern portion of Spur Road west toward inlet (vehicle free March 15 to September 14)
- Hatteras Inlet to (new) ramp 59.5 (year-round)
- (New) ramp 63 to 1.0 mile northeast of ramp 67 (year-round)

- 0.5 mile northeast of ramp 68 to ramp 68 (Ocracoke Campground area) (vehicle free April 1 to October 31)
- Ramp 68 to 0.4 miles northeast of ramp 70 (includes Ocracoke Day Use area) (year-round)

Pedestrian use would be permitted in these areas, and all of these areas would be subject to resource closures for breeding, nesting, and fledging activities, as detailed in table 10-1. In addition, when scrape(s), nest(s), or chick(s) occur in the immediate vicinity of paved roads, parking lots, campground, buildings, and other facilities, such as within villages or at NPS developed sites, the NPS would retain the discretion to provide resource protection to the extent possible, while still allowing those facilities to remain operational. Regardless of the nature of the adjacent facilities, in all cases, as a minimum, the NPS would provide signs, fencing, and reduced buffers to protect nest(s) and chick(s) once they occur. The NPS would not reduce buffers to accommodate an ORV corridor or ORV ramp access. This management would provide the Seashore flexibility in species management in these areas but may have long-term minor adverse impacts to piping plover, as this species would not be expected to use habitat in these areas, but if they did could experience disturbance.

Piping plovers would likely experience long-term moderate benefits from the size of the resource closures under alternative F, including establishment of prenesting closures, and the fact that buffers would adjust in response to chick mobility, as these action would be expected to improve the sustainability of the species at the Seashore.

*Management of Wintering/Nonbreeding Populations.* Management of wintering/nonbreeding populations of piping plover under alternative F would be similar to the measures described under alternative C, except nonbreeding shorebird SMAs would not be established. Under alternative F the VFAs, shown on the maps in chapter 2, would provide for additional areas for nonbreeding species. These areas are relatively less disturbed to allow for foraging, resting and roosting. Also, an annual habitat assessment would be conducted at the points and spits after all birds have fledged from the area. Prior to removing the prenesting closures, resource closures would be established in the most sensitive portions of nonbreeding shorebird habitat in these areas, based on habitat used by winter piping plovers in more than one (i.e., two or more) of the past five years. People and pets would be prohibited within these closures. The establishment of VFAs that provide areas without ORV disturbance (although people would still be permitted in these areas) would result in long-term moderate beneficial impacts to nonbreeding piping plover that would be greater than those under alternatives A or B.

*Education and Outreach.* Under alternative F, education and outreach activities would be the same as those described under alternative A, with the addition of educational requirements as part of a permit program. A new voluntary resource education program would also be implemented that would be focused toward pedestrian beach users. This additional education would result in long-term minor to moderate benefits to species as the public is provided with more information regarding piping plover management issues.

*Overall Impacts from Resources Management Activities.* Overall impacts under alternative F from resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term moderate and beneficial for piping plovers. As with all species management activities, minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of prenesting closures early in the breeding season, VFAs and areas seasonally closed to ORV use, monitoring activities, and establishment of prescribed buffers would provide long-term moderate beneficial impacts to the species. Long-term moderate benefits to nonbreeding populations would be greater under alternative F than under alternatives C or E because of the addition of VFAs combined with the nonbreeding closures.

**ORV and Other Recreational Use**

*ORV and Pedestrian Access.* Under alternative F, Seashore visitors would be provided with a degree of predictability regarding areas available for ORV use, as well as VFAs, based largely on the seasonal resource and visitor use characteristics of various areas in the Seashore. Under alternative F, approximately 28 miles of shoreline would be designated for ORV use year-round, approximately 13 miles would be seasonally designated for ORV use from November 1 to March 31 (with two areas from September 15 to March 14), and approximately 26 miles would be designated as vehicle free year-round. The speed limit would be 15 mph unless otherwise posted, and permits would be required for all ORVs, except for authorized commercial vehicles as described below. Where ORV use is permitted and there are prenesting closures, an ORV corridor would be established seaward of the prenesting closure that would be 35 meters (115 feet) rather than the 50-meter (164-foot) corridor during the nonbreeding season. subject to resource closures. All buffers, including prenesting closures, would not be reduced to accommodate an ORV corridor or ORV access ramp.

Establishment of various VFAs, both year-round and seasonally, as well as the standardized monitoring and buffers in areas where ORV are permitted would reduce pressure from recreational activities on piping plover. Under alternative F, this reduction in pressure would be similar to alternative E and greater than alternatives A and B, but less than C and D, which close larger and more contiguous areas of habitat for longer periods of time. As noted in chapter 3, a 3-year study on Cape Cod and Fire Island, New York (Kluft and Ginsberg 2009), found that higher ORV traffic resulted in dispersal and desiccation of the wrack line, thereby reducing the population of invertebrates in that area. Alternative F would allow for beach driving in the wrack during the day outside of VFAs, but would maintain nighttime closures and limit driving during the day where VFAs are established reducing disturbance in these areas seasonally and year-round. Overall impacts to invertebrates would be long-term and minor (as discussed later in this chapter), and would reduce the food source available to birds at the Seashore, but to a lesser degree than if night driving was permitted, resulting in long-term minor impacts.

Like alternative E, alternative F would reduce the potential for disturbance and nest abandonment from direct short-term contact with people and/or essential vehicles compared to alternatives A and B, but would have greater impacts than alternative C due to the existence of an ORV corridor at Cape Point and South Point under alternative F. Although the establishment of prenesting closures, designation of year-round and seasonal VFAs and the other restrictions under alternative F should limit adverse impacts to piping plover, compliance with closures may not be absolute, since alternative F still includes pedestrian access to Bodie Island Spit and a conduit (ORV corridor) to Cape Point and South Point during the breeding season (all subject to resource closures). Therefore, recreational uses could result in short-term minor to moderate adverse impacts to piping plovers if non-compliance occurs. Since recreational activities would still occur, under alternative F impacts from ORV and pedestrian access to piping plover would be long-term minor to moderate adverse and would be greater than alternative C due to increased access.

*Night-Driving Restrictions.* Under alternative F, all nonessential ORV traffic would be prohibited from all areas (other than soundside access areas), from 9:00 p.m. until 7:00 a.m. from May 1 to November 15. From November 16 to April 30, ORV use would be allowed 24 hours per day in designated ORV routes for vehicles with a valid ORV permit. Furthermore, the NPS would retain the discretion to limit night driving to certain areas or routes, based on resource protection considerations. Because plovers are known to be active at night (Staine and Burger 1994; Majka and Shaffer 2008), and plover chick and fledgling response to vehicles can increase their vulnerability to ORVs (USFWS 1996a, 2009a), the high level of protection at night from May 1 to November 15 under alternative F would result in long-term moderate beneficial impacts because it would reduce the potential for disturbance to plovers that could result in mortality.

*Authorized Commercial Vehicles.* Authorized commercial vehicles, including commercial use authorization holders and commercial fishermen, would not require a separate ORV permit. Commercial fishermen would be able to enter all areas except resource closures and lifeguarded beaches. The superintendent may allow commercial fishing vehicles to enter the beach at 5:00 a.m. when night driving restrictions are in place for the general public, per the conditions outlined in table 8. Similar to alternative C, alternative F would have long-term negligible adverse impacts from the presence of commercial fishing operations and long-term minor to moderate benefits from night-driving restrictions.

*Permits/Carrying Capacity.* As described above under the night-driving restrictions and education/outreach sections, alternative F would require a permit for ORV use, including night driving. As stated in these sections, as a result of the educational information provided by the permit, there would be long-term minor to moderate benefits to piping plover as ORV users would be more aware of the regulations in place to protect these species, which would likely result in a higher level of compliance with buffer, closures, and other restrictions. There would be no impacts related to carrying capacity, as described under alternative C.

*Pets/Other Recreational Activity Restrictions.* Pets would be permitted in the Seashore, except ORV corridors at Cape Point and South Point and in pedestrian shoreline access areas front of (i.e., seaward of) prenesting areas in accordance with 36 CFR 2.15, which applies to all units of the national park system and prohibits pet owners from “failing to crate, cage, restrain on a leash which shall not exceed 6 feet in length, or otherwise physically confine a pet at all times.” These measures would reduce the likelihood of pet disturbance in piping plover breeding areas; however, compliance is needed to ensure that this reduces the risk of impacts. Camping and beach fire restrictions would be the same as those under alternative C, with the exception that beach fires would be restricted from 10:00 p.m. to 6:00 a.m. year-round and from May 1 to November 15 (the sea turtle nesting season) would only be permitted in front of Coquina Beach, Rodanthe, Waves, Salvo, Avon, Buxton, Frisco, Hatteras Village, and Ocracoke Day Use Area. These additional restrictions would result in long-term moderate beneficial impacts to piping plover at the Seashore as recreational pressures are further reduced.

*Overall Impacts from ORV and Other Recreational Use.* Overall impacts under alternative F from ORV and other recreational use would be long-term minor to moderate adverse. The establishment of prenesting closures and year-round and seasonal VFAs which proactively reduce or preclude recreational use early in the breeding season, ORV permit requirements, and pet and other recreational activity restrictions would all provide benefits in terms of species protection. As alternative F would provide for more flexible access to various areas of the Seashore, the potential for disturbance to piping plover is increased over alternatives C and D, resulting in long-term minor to moderate adverse impacts.

**Cumulative Impacts.** The same past, present, and future actions discussed under the cumulative impact scenario for alternative A would occur under alternative F. The overall cumulative impact of these past, current, and future actions, would be long-term negligible to minor, depending on the intensity and duration of unpredictable factors such as storm events, with long-term moderate beneficial impacts from actions such as increased interpretive programs as part of the long-range interpretive plan and predator management within the Seashore. Many of these actions do not directly impact piping plover habitat in the area, as most of this habitat is located within the Seashore and is impacted by NPS management actions more than any of the aforementioned past, present, and future actions. These impacts, combined with the long-term minor to moderate adverse, as well as minor to moderate beneficial impacts of alternative F, would be long-term minor to moderate adverse impacts, as actions within the Seashore would act as a driver for overall cumulative impact.

**Conclusion.** Overall impacts under alternative F from resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term moderate and beneficial

for piping plovers. As with all species management activities, minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of prenesting closures early in the breeding season, year-round and seasonal VFAs, monitoring activities, and establishment of prescribed buffers would provide long-term moderate beneficial impacts to the species. Long-term moderate benefits to nonbreeding populations would be greater under alternative F than under alternatives C or E because of the addition of the year-round VFAs. Overall impacts under alternative F from ORV and other recreational use would be long-term minor to moderate adverse. The establishment of the prenesting closures and year-round and seasonal VFAs which proactively reduce or preclude ORV use throughout the breeding season, ORV permit requirements, and pet and other recreational activity restrictions would all provide benefits in terms of species protection. As alternative F would provide for more flexible access to various areas of the Seashore, the potential for disturbance to piping plover is increased over alternatives C and D, resulting in long-term minor to moderate adverse impacts.

Cumulative impacts would be long-term minor to moderate adverse.

**Determination of Effect.** Under the ESA, the actions taken under alternative F may affect / are likely to adversely affect piping plover due to the minor adverse effects from monitoring and surveying and the minor to moderate impacts from ORV and other recreational use. Under alternative F, year-round and seasonal VFAs would provide protection for migrating piping plover and plover establishing territories early in the season. However, recreational uses would still occur in the vicinity of plovers during breeding season in areas such as Cape Point and South Point. Under alternative F, nonessential ORV traffic would be prohibited from all areas (other than the soundside access areas), from 9:00 p.m. to 7:00 a.m. from May 1 to November 15. From November 16 to April 30, ORV access would be allowed 24 hours per day in designated ORV routes for vehicles displaying a valid ORV permit. The NPS retains the discretion to limit night driving to certain areas or routes, based on resource protection considerations. These restrictions to night driving would provide long-term minor to moderate benefits to piping plovers but could still result in long-term minor adverse impacts during the time when night driving is allowed by permit. These impacts would result in a finding of may affect / are likely to adversely affect piping plovers under the ESA because the action would result in direct or indirect impacts to the species that are not discountable, insignificant, or beneficial. And while there may be beneficial impacts from surveys and monitoring, and management of recreation, the actions under alternative F would also likely cause some adverse effects.

Under the ESA, the actions taken under alternative F may affect / are not likely to adversely affect designated critical habitat for wintering piping plover due to the establishment of VFAs which would result in the closure of approximately 26 miles of shoreline to ORV use year round. These closures would provide less-disturbed foraging, resting, and roosting areas for migrating and wintering shorebirds and would protect the primary constituent elements of intertidal sand beaches and ocean backshores. These year-round VFAs along the ocean shoreline would be managed to allow for pedestrian use. Nonbreeding resource closures would also be established at the points and spits based on an annual habitat assessment, which would provide protection for wintering plover habitat. There would be some benefit to the critical habitat from the implementation of seasonal night-driving restrictions although these restrictions would only apply between May 1 and November 15, which would not cover the majority of time when the wintering population of piping plover is present at the Seashore.

Although there would be construction of ORV access ramps, parking areas, and interdunal roads, none of these improvements would impact any of the primary constituent elements of designated critical habitat for wintering piping plover.

Implementation of alternative F would result in a finding of may affect / is not likely to adversely affect designated critical habitat for wintering piping plover under the ESA because the action would result in

impacts to the critical habitat for the species that are discountable, insignificant, or beneficial. Actions under alternative F would result in greater protection of the primary constituent elements of suitable interior habitat, spits, intertidal sand beaches, and ocean backshore, primarily as a result of the establishment of nonbreeding resource closures, and approximately 26 miles of year-round VFAs.

**TABLE 52. SUMMARY OF IMPACTS TO PIPING PLOVER UNDER THE ALTERNATIVES**

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
<b>Resources Management Activities</b>					
Establishment of Prenesting Closures					
Long-term minor to moderate adverse impacts would occur to piping plovers arriving before the April 1 prenesting closures due to the sensitivity of the species during this life stage, with long-term moderate benefits to those arriving after the prenesting closure is in place.	Long-term moderate benefits would occur as closures would be in place earlier to provide protection for migratory piping plovers and breeding plovers establishing territories.	Long-term moderate benefits would occur as closures would be in place to provide protection for migratory piping plovers and breeding plovers establishing territories early in the breeding season.	Long-term moderate benefits would occur as closures would be in place to provide protection for migratory piping plovers and breeding plovers establishing territories early in the breeding season.	Long-term moderate benefits would occur as closures would be in place to provide protection for migratory piping plovers and breeding plovers establishing territories early in the breeding season.	Long-term moderate benefits would occur as prenesting closures would be established by March 15 to provide protection for migratory piping plovers and breeding plovers establishing territories.
Surveying and Monitoring					
Best management practices would be implemented to reduce disturbance during surveying, resulting in long-term minor to moderate benefits to the species as surveying and monitoring would lead to the necessary management measures.	Intensive surveys and monitoring would be expected to have long-term moderate beneficial impacts, as any changes in species behavior would be detected and appropriate management measures implemented.	Surveys and monitoring would be expected to have long-term moderate beneficial impacts, as these actions would improve the sustainability of the species at the Seashore.	Surveys and monitoring would be expected to have long-term moderate beneficial impacts, as these actions would improve the sustainability of the species at the Seashore.	Surveys and monitoring would be expected to have long-term moderate beneficial impacts, as these actions would improve the sustainability of the species at the Seashore.	Surveys and monitoring would be expected to have long-term moderate beneficial impacts, as these actions would improve the sustainability of the species at the Seashore.

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
<b>Buffer/Closure Establishment</b>					
Piping plovers would likely experience minor long-term benefits from the size of resource closures and observation intensity would adjust in response to chick behavior. Long-term moderate adverse impacts may occur as frequent adjustment of the buffers may result in additional disturbance to piping plover, and buffers that are not adjusted in a timely manner could result in less than optimal protection for the species.	The larger and more responsive buffers under alternative B would be expected to have long-term minor to moderate beneficial effects to piping plover.	Establishment of SMAs and prescribed buffers, along with periodic review to ensure effective management would have long-term moderate beneficial impacts.	SMAs would be closed to public access during the breeding season and closed to ORVs year-round, resulting in long-term moderate to major beneficial impacts from species closures and buffers. Benefits would also occur from a system of periodic review that would evaluate the SMAs for effectiveness.	Establishment of SMAs and prescribed buffers, along with periodic review to ensure management is effective, would have long-term moderate beneficial impacts.	Establishment of prenesting closures and prescribed buffers along with periodic review to ensure management is effective, would have long-term moderate beneficial impacts. Establishment of VFAs would also provide additional relatively less disturbed areas for piping plover, although pedestrian access would still be permitted.
<b>Management of Wintering/Nonbreeding Populations</b>					
Suitable interior habitats at spits and at Cape Point would be closed year-round to all recreational users and would provide for resting and foraging for all species, resulting in long-term minor beneficial impacts as this would represent a improvement to habitat during key life stages of the species.	Closing suitable interior habitats year-round at spits and Cape Point, as well as implementation of SECN survey protocol, would have long-term moderate beneficial impacts for piping plover.	Annual habitat assessment and establishment of nonbreeding SMAs would result in long-term moderate beneficial impacts.	Annual habitat assessment and establishment of nonbreeding SMAs would result in long-term moderate beneficial impacts.	Annual habitat assessment and establishment of nonbreeding SMAs would result in long-term moderate beneficial impacts.	Annual habitat assessment and establishment of nonbreeding resource closures would result in long-term moderate beneficial impacts. Long-term moderate benefits to nonbreeding populations would be greater under alternative F than alternatives C or E because of the addition of VFAs that would be closed to ORV year round and provide relatively less disturbed habitat for foraging, resting, and roosting.

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
<b>Education and Outreach</b>					
Education and outreach efforts under alternative A would aim to reduce non-compliance and further protect the species, resulting in long-term minor beneficial impacts.	Public outreach as part of species management would have long-term minor beneficial impacts, with the expanded outreach having greater impacts than alternative A.	Additional education would result in long-term minor to moderate benefits to species as the public is provided with more information regarding this issue.	Additional education would result in long-term minor to moderate benefits to species as the public is provided with more information regarding this issue.	Additional education would result in long-term minor to moderate benefits to species as the public is provided with more information regarding this issue.	Additional education would result in long-term minor to moderate benefits to species as the public is provided with more information regarding this issue.
<b>Overall Impacts from Resources Management Activities</b>					
Overall, impacts to piping plover from resource management activities (primarily as a result of surveys and field activities) would be long-term minor to moderate adverse. Although the management of the species would provide a certain level of benefit, the manner in which buffers would be established, along with the need to adjust buffers frequently would have an adverse impact on the species.	Overall, impacts under alternative B from resource management activities (primarily resulting from the effects of surveying and field activities) would be long-term minor to moderate beneficial. Buffers for piping plover would be larger and provide more protection compared to buffers under alternative A. Minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of prenesting closures early in the breeding season, monitoring activities, education and outreach efforts, and establishment of prescribed buffers would provide long-term minor to moderate beneficial impacts to the species.	Overall impacts under alternative C from resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term moderate beneficial. As with alternative B, minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of SMAs early in the breeding season, monitoring activities, and establishment of prescribed buffers would provide long-term moderate beneficial impacts to the species.	Overall impacts to piping plover from resources management activities (primarily resulting from the effects of surveying and field activities) under alternative D would be long-term moderate to major beneficial. As with all species management activities, minor adverse impacts would occur from human presence during monitoring, but on the whole the implementation of SMAs that prohibit ORV use year-round and only allow pedestrian access outside of the breeding season, establishment of prenesting closures early in the breeding season, monitoring activities, and establishment of prescribed buffers would provide long-term moderate to major beneficial impacts to the species.	Overall impacts under alternative E from resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term moderate beneficial. As with all species management activities, minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of SMAs early in the breeding season, monitoring activities, and establishment of prescribed buffers would provide long-term moderate beneficial impacts to the species.	Overall impacts under alternative F from resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term moderate and beneficial for piping plovers. As with all species management activities, minor adverse impacts would occur from human presence during monitoring activities, but on the whole the establishment of prenesting closures monitoring activities, and establishment of prescribed buffers would provide long-term moderate beneficial impacts to the species. Long-term moderate benefits to nonbreeding populations would be greater under alternative F than under alternatives C or E because of the additional year-round VFAs.

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
<b>ORV And Other Recreational Use</b>					
ORV and Pedestrian Access					
A lack of compliance with closures, including non-compliance (either intentional or unintentional) due to variable buffer sizes, could result in short-term moderate to major adverse impacts at a particular location, and would result in long-term moderate to major adverse impacts if there is a chronic lack of compliance.	Increased monitoring at key piping plover breeding areas and larger buffers for piping plover chicks would offer more protection from ORV and pedestrian access. However, because the ocean and inlet shoreline and existing soundside routes would be designated as ORV routes year round, subject to resource closures, the potential for impacts to piping plover from recreational use would still exist, resulting in long-term moderate adverse impacts.	Establishment of SMAs and prescribed buffer areas and exclusion of ORVs from these areas during the breeding season would reduce pressure on the species from recreational uses at the Seashore. Under this alternative, recreational activities would still occur in the vicinity of the species and would still have the potential to impact them, with long-term minor to moderate adverse impacts to piping plover from recreational use, and minor to moderate benefits from the protection offered.	Due to the restrictions on recreational activities in SMAs (ORVs prohibited year-round; pedestrians prohibited during breeding season), adverse impacts from recreational use would be expected to be long-term minor adverse.	Although the large SMAs would be beneficial to the species, continued recreation use in this area would still result in potential long-term minor to moderate adverse impacts to the species, which would be greater than those impacts under alternative C because of the increased access from ORV pass-throughs and shorter duration of closures within SMAs.	The species would benefit from the proactive protection provided by prenesting closures, establishment of buffers, and from the year-round and seasonal VFAs. The VFAs would provide additional areas without ORV disturbance or disturbance from the increased numbers of pedestrians carried by ORVs into the more remote areas of the Seashore. Continued recreation use in this area would still result in potential long-term minor to moderate adverse impacts to the species.
Night-Driving Restrictions					
Allowing unrestricted night driving would result in long-term moderate adverse impacts, as plovers are known to forage along the shoreline at all times of the day.	Restrictions on night driving would be provide long-term minor to moderate benefits to piping plovers; however, could still result in long-term minor adverse impacts during the time when night driving is allowed (until 10:00 p.m. during much of the breeding season).	The high level of protection at night from May 1 to November 15 would result in long-term moderate beneficial impacts because it would reduce the potential for disturbance to plovers that could result in mortality.	The high level of protection at night from May 1 to November 15 would result in long-term moderate beneficial impacts because it would reduce the potential for disturbance to plovers that could result in mortality.	Night-driving restrictions under alternative E would result in long-term minor to moderate beneficial impacts because it would reduce the potential for disturbance to plovers that could result in mortality, but would still allow some level of night driving after dark (until 10:00 p.m. between May 1 and November 15).	Alternative F would result in long-term moderate beneficial impacts because it would reduce the potential for disturbance to plovers that could result in mortality.

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
<b>Commercial Fishing</b>					
There would be long-term negligible adverse impacts from commercial fishing.	Presence of commercial fishing operations would have a long-term negligible adverse impact, with long-term minor to moderate beneficial impacts from night-driving restrictions.	Presence of commercial fishing operations would have a long-term negligible adverse impact, with long-term minor to moderate benefits from night-driving restrictions.	Presence of commercial fishing operations would have a long-term negligible adverse impact, with long-term minor to moderate benefits from night-driving restrictions.	Presence of commercial fishing operations would have a long-term negligible adverse impact, with long-term minor to moderate benefits from night-driving restrictions.	Presence of commercial fishing operations would have a long-term negligible adverse impact, with long-term minor to moderate benefits from night-driving restrictions.
<b>Permit/Carrying Capacity Requirements</b>					
Lack of a permit system would have long-term moderate adverse impacts. Lack of a carrying capacity is not expected to impact piping plover.	There would be no impacts related to carrying capacity, as it would not be a requirement under this alternative.	ORV permit requirements would result in long-term minor to moderate benefits due to the species protection resulting from the educational component of the permit. There would be no impacts related to carrying capacity.	ORV permit requirements would result in long-term minor to moderate benefits due to species protection resulting from the educational component of the permit. There would be no impacts related to carrying capacity.	ORV permit requirements would result in long-term minor to moderate benefits due to species protection resulting from the educational component of the permit. There would be no impacts related to carrying capacity.	ORV permit requirements would result in long-term minor to moderate benefits due to species protection resulting from the educational component of the permit. There would be no impacts related to carrying capacity.
<b>Pet/Other Recreational Activity Restrictions</b>					
Long-term minor benefits from camping and nighttime beach fire restrictions. Long-term minor to moderate adverse impacts from presence of pets at the Seashore during breeding season.	Long-term minor benefits from camping and nighttime beach fire restrictions. Long-term minor to moderate adverse impacts from presence of pets at the Seashore during breeding season.	Restrictions on pets, camping, and beach fires and additional education from a beach fire permit, would be expected to have long-term minor to moderate benefits to species at the Seashore, further reducing pressure to piping plover from recreational activity.	Prohibition of pets within the SMAs year-round and additional education from a beach fire permit would be expected to have long-term minor to moderate beneficial impacts to the species, greater than those under alternative C, provided the level of non-compliance is kept low.	These restrictions would result in long-term minor to moderate benefits to species at the Seashore, further reducing pressure to piping plover from recreational activity, with the potential for long-term minor to moderate adverse impacts from the park-and-stay option.	Additional beach fire restrictions and prohibition of pets in resource closures and in front of prenesting areas would result in long-term moderate beneficial impacts to species at the Seashore as recreational pressures are further reduced.

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
Overall Impact from ORV and Other Recreational Use					
<p>Overall, impacts to piping plover from ORV and other recreational use would be long-term moderate to major adverse as much of the Seashore would be open to recreational use, with an increased potential that piping plover could be impacted due to disturbance from ORV use and other recreational activities. Lack of a permit system for education and law enforcement, no night-driving restrictions, and lack of compliance with pet leash requirements would contribute substantially to these adverse impacts.</p>	<p>Overall, impacts to piping plover from ORV and other recreational use would be long-term moderate adverse. While some buffers would be increased in an attempt to separate recreational uses from piping plover, access up to these buffers would be provided at all Seashore beaches and could result in intentional or unintentional non-compliance (i.e., when signs are washed out), which would impact the species. Adverse impacts would also occur due to limited prenesting protection outside of the points and spits, and the potential for protective buffers to be reduced during critical life stages of plover chicks.</p>	<p>Overall, impacts to piping plover from ORV and other recreational use would be long-term minor adverse. The establishment of the SMAs which proactively reduce or preclude recreational use early in the breeding season, ORV permit requirements, seasonal night-driving restrictions, and pet and other recreational activity restrictions would all provide benefits in terms of species protection. As there would still be some opportunity for recreational use to come in contact with and impact piping plovers, and the fact that alternative C would still include some level of pedestrian access to three SMAs during a portion of the breeding season, impacts to piping plover would be long-term minor adverse.</p>	<p>Overall impacts from ORV and other recreational use would be long-term minor adverse. The establishment of SMAs that are closed to ORVs year-round and managed under ML1 procedures during the breeding season would proactively preclude recreational use early in the breeding season from large areas of the Seashore, which would reduce the potential for disturbance to plovers during critical life stages. This protection, combined with ORV permit requirements, seasonal night-driving restrictions, and pet and other recreational activities restrictions would all provide benefits in terms of species protection. As there would still be some opportunity for recreational use to come in contact with and impact the species, impacts would be long-term minor adverse.</p>	<p>Overall impacts from ORV and other recreational use would be long-term minor to moderate adverse. The establishment of the SMAs which proactively reduce or preclude recreational use early in the breeding season, ORV permit requirements, and pet and other recreational activity restrictions would all provide benefits in terms of species protection. Although there would be benefits from seasonal night-driving restrictions, they would not be as great as other action alternatives because driving after dark (until 10:00 p.m.) would still be occurring, even during seasonal restrictions. The potential for adverse impacts would exist from the park-and-stay option under this alternative. As there would still be some opportunity for recreational use to come in contact with and impact the species, impacts would be long-term minor to moderate adverse.</p>	<p>Overall impacts under alternative F from ORV and other recreational use would be long-term minor to moderate adverse. The establishment of prenesting closures, year-round and seasonal VFAs, ORV permit requirements, and pet and other recreational activity restrictions would all provide benefits in terms of species protection. As alternative F would provide for more flexible access to various areas of the Seashore, the potential for disturbance to piping plover is increased over alternatives C and D, resulting in long-term minor to moderate adverse impacts.</p>

## SEA TURTLES

### Species-specific Methodology and Assumptions

Potential impacts on federally listed sea turtle populations and their habitat within the Seashore were evaluated based on the species' known interactions with humans, domestic pets, recreational and nighttime activities, predators, artificial lighting, and ORVs, as well as past and present occurrence at the Seashore. Information about habitat and species occurrence within the Seashore and potential impacts on sea turtles from recreation and other activities was acquired from staff at Cape Hatteras National Seashore, the USFWS, the NCWRC, and available literature.

Although five threatened or endangered sea turtle species occur in the waters of North Carolina, only three species, the loggerhead, green, and leatherback, are known to nest at the Seashore. The other two species, Kemp's ridley and hawksbill, are only known to occur at the Seashore through occasional stranding, usually due to either prior death or incapacitation from hypothermia. Therefore, the analysis focuses only on the three species that nest at the Seashore. For these three species, the analysis focuses on effects to sea turtles from a variety of human recreation and other activities, as well as impacts incurred as a result of surveying and management activities. Except for the timing of nest laying activities, the nesting habits for loggerhead, green, and leatherback sea turtles at the Seashore are similar. Therefore, the analysis generally discusses the impacts on the sea turtles as a group. Impacts to a specific species are noted where they differ from impacts to the other sea turtle species. Sea turtle nesting habitat overlap protected bird species and seabeach amaranth habitat seaward of the primary dune line. Consequently, management of these species could also benefit nesting sea turtles and is included in the analysis. However, the extent to which the bird and seabeach amaranth closures are beneficial to the turtles depends on the location, size, and duration of the closures. In the analysis, it is assumed that compliance with closures and other regulations such as leash requirements, disposal of bait and fish carcasses, etc., would increase from current levels where alternatives increase the natural resource and law enforcement staff.

When examining the impacts of artificial light on sea turtles, the lighting zones (see "Visitor Use and Experience")—developed for the Seashore by the NPS Night Skies Team—were considered. In these zones, special consideration is given to areas with sensitive wildlife, and alternate guidance is provided to enhance the protection of nocturnal habitat. These special lighting zones represent the conditions that should be present at the Seashore, not necessarily actual current conditions, and create a buffer when two varying zones abut each other.

In general, direct and indirect impacts to sea turtles, their nests, eggs, and hatchlings would primarily occur during the sea turtle nesting and hatching seasons from May 1 to November 15 and during summer and fall storm events when post-hatchlings may wash ashore. Direct impacts to live stranded turtles may occur year-round.

The information contained in this analysis was obtained through best professional judgment of Seashore staff and experts in the field, and by reviewing applicable scientific literature.

## Sea Turtle Impact Thresholds

A summary of sea turtle impacts under all alternatives is provided in table 53 at the end of this section. The following thresholds for evaluating impacts to sea turtles were defined.

*Negligible:* There would be no observable or measurable impacts to sea turtles, their habitats, or the natural processes sustaining them. Impacts would be well within the natural range of variability.

*Minor Adverse:* Impacts to sea turtles, their habitats, or the natural processes sustaining them would be detectable, but would not be outside the natural range of variability. Disturbance to some nesting females could be expected to occur, but would be infrequent. Complete or partial nest loss due to human activities would occur infrequently. Occurrences of disorientation/disruption of hatchling movement would occur infrequently (less than 10% of all hatchling emergence events). Direct hatchling mortality from human activities would be rare.

*Minor Beneficial:* Impacts on sea turtles, their habitats, or the natural processes sustaining them would be detectable, but would not be outside the natural range of variability. Improvements to key characteristics of habitat and/or protection to key life history stages in the Seashore would sustain or slightly improve existing population levels, population structure, or other factors and maintain a sustainable population in the Seashore.

*Moderate Adverse:* Impacts to sea turtles their habitats or the natural processes sustaining them would be detectable and could be outside the natural range of variability. Occasional disturbance to some nesting females could be expected, with negative impacts to reproduction affecting local population levels. Complete or partial nest loss due to human activities would occur occasionally. Occurrences of disorientation/disruption of hatchling movement would occur occasionally (more than 10% and less than 30% of all hatchling emergence events). Direct hatchling mortality from human activities would occasionally occur. However, sufficient population numbers and habitat in the Seashore would remain functional to maintain a sustainable population in the Seashore.

*Moderate Beneficial:* Impacts on sea turtles, their habitats, or the natural processes sustaining them would be detectable and could be outside the natural range of variability. Changes to key characteristics of habitat in the Seashore and/or protection to key life history stages would minimize or prevent harassment or injury to individuals and improve the sustainability of the species in the Seashore.

*Major Adverse:* Impacts to sea turtles, their habitats, or the natural processes sustaining them would be detectable and would be expected to be outside the natural range of variability. Frequent disturbance to nesting females would be expected, with negative impacts to reproduction, or other factors resulting in a decrease in Seashore population levels or a failure to restore levels that are needed to maintain a sustainable population in the Seashore. Impacts could include in direct mortality to one or more nesting females. Complete or partial nest loss due to human activities would occur frequently. Occurrences of disorientation/disruption of hatchling movement would occur frequently (more than 30% of all hatchling emergence events). Direct hatchling mortality from human activities would frequently occur. Local population numbers, population structure, and other demographic factors might experience large declines.

*Major Beneficial:* Impacts on sea turtles, their habitats in the Seashore, or the natural processes sustaining them during key life history stages would be detectable and would be expected to be outside the natural range of variability. Changes to key characteristics of habitat in the Seashore and/or protection to key life history stages would substantially lessen mortality or loss of habitat and would result in notable increases in Seashore population levels.

*Duration:* Short-term effects would last up to two seasons.

Long-term effects would be continued beyond two seasons.

## Study Area

The study area for assessment of the various alternatives is the Seashore. Based on the fact that the loggerhead sea turtle is the primary nester within the Seashore (94% of all nests [NPS 2007e, 2008a; Baker pers. comm. 2009a]) and is the only sea turtle for which recovery criteria are designated for the state of North Carolina in its recovery plan (NMFS and USFWS 2008, 1992a, 1992b, 1991), the study area for the cumulative impacts analysis is the state of North Carolina.

## Impacts of Alternative A: No Action—Continuation of Management under the Interim Protected Species Management Strategy

### Resources Management Activities

Under alternative A, Seashore staff would survey the entire Seashore daily for turtle crawls and nests from May 1 to September 15. Daily surveys would be conducted in the morning prior to the onset of heavy public ORV use. This period encompasses the nesting season for loggerhead sea turtles (mid-May to mid-August), the most prevalent nesters at the Seashore, and the vast majority of the nesting season for the green and leatherback sea turtles, which are infrequent nesters at the Seashore. Prior to May 1, the leatherback sea turtle is the only species likely to nest at the Seashore. Although turtle surveying would not occur prior to May 1, turtle crawls may be detected by bird monitors as evidenced by single leatherback nests being detected in April during two previous years (NPS 2001c, 2008a). Additionally, turtle crawls were often detected by bird monitors in May during years when daily turtle surveys did not begin until June 1 (Murray pers. comm. 2008).

From September 16 to November 15, Seashore staff would conduct periodic monitoring (e.g., every two to three days) for hatchlings emerging from previously undetected nests, especially in areas of high

visitation. Between 1998 and 2009, 4 nests have been found after August 31, three of which were found on September 15 or later. However, prior to 2007, morning nest surveys ended on August 31, so any nests laid after that time were unlikely to be located and protected. Since 2007, nest surveys have continued to September 15 (Baker pers. comm. 2009b). Although regular monitoring occurs, some nests on a rare occasion may be missed due to human error or from evidence of the nest being covered up by nighttime ORV use (NPS 2005c, 2004d). Nests that go undetected would not be subject to management by the Seashore staff and would result in long-term minor to moderate adverse impacts because the nests would be subject to multiple potential threats such as being run over by ORVs, depredation by foxes or other predators, and loss due to erosion or frequent flooding. Hatchlings emerging from unprotected nests would be at a greater risk from light pollution because there would be no light management measures enacted. If an undetected nest were located in an ORV or day use area, hatchlings would be subjected to impacts associated with tire tracks and footprints because these would not be raked smooth by Seashore staff. If tracks are not raked smooth, hatchlings can become easily trapped and disoriented in the ruts/footprints, leading to an increased risk of death by predation, being run over by subsequent ORV traffic, or exhaustion prior to reaching the ocean.

Seashore staff would use ATVs/UTVs and occasionally ORVs to survey for turtle crawls and nests. Throughout the Seashore, essential vehicle use would not exceed 10 mph and would avoid driving within turtle nest closures. The use of ATVs/UTVs and ORVs during turtle surveys would provide long-term moderate benefits by allowing Seashore staff to cover the entire length of the shoreline each morning in search of turtle crawls and nests prior to the onset of heavy public use during the daytime hours. Without the use of these vehicles, staff would not be able to cover the entire Seashore or bring the necessary supplies with them to install closures around located nests. NPS staff using vehicles would not leave tire ruts behind in nesting areas. Using ATVs/UTVs and ORVs during surveys would cause a slight risk of crushing a nest or hatchlings or disturbing nesting turtles, potentially causing long-term minor to moderate adverse impacts. However, these risks would be minimized by the fact that surveys would occur during the morning, while nesting and hatching typically occur at night, as well as the precautions taken by the experienced staff conducting the surveys. On the rare occasion when nesting or hatching activities occur during daylight hours, as happened in 2005 (Sayles pers. comm. 2005), abiding by the speed and closure limits would allow observers to see and avoid impacting the turtles and their nests.

Daily surveys for nests would provide long-term minor to moderate beneficial impacts. It would allow the timely detection of closure violations and repair of damage (e.g., broken signs or string) caused by ORVs or pedestrians and allow for an assessment of whether any damage to a nest occurred. Tracks left behind by ORVs and/or pedestrians that are detected would be raked smooth. Predator activity and hatching events would also be detected. In the case of predator activity, daily surveys would allow staff to protect those nests with predator exclosures.

During periods following severe storm events or when large quantities of seaweed are washed ashore, monitoring for post-hatchling washbacks would occur. This monitoring would provide long-term minor benefits to hatchlings washed ashore by helping prevent them from being run over by vehicles or disturbed by pedestrians or their pets and by protecting them from potential predation.

Under alternative A, the Seashore would install a 30-foot (9.1-meter) by 30-foot (9.1-meter) buffer around each turtle nest found. This buffer would continue to help protect turtle nests from being run over by ORVs or disturbed by pedestrians or pets. The buffers would also protect the nests from potential erosion impacts caused by multiple ORV passes. After approximately 50 to 55 days, the turtle closure would be expanded to the surf line, with varying widths based on the level and type of recreational use in the area. In VFAs with little or no pedestrian traffic, the total width would be 75 feet (22.9 meters); on village beaches or other areas with high levels of pedestrian and other non-ORV use, the total width would be 150 feet (45.7 meters); and in ORV traffic areas, the total width would be 350 feet (106.7

meters). Additionally, the closed area would be expanded by 30 feet (9.1 meters) to 50 feet (15.2 meters) on the landward side of the nest. By protecting all of the detected turtle nests in the Seashore during the incubation and hatching periods, these buffers would provide long-term moderate to major beneficial impacts to the sea turtles.

As nests near their hatching date, Seashore staff would continue to install U-shaped light-filter fencing around the nests, with the open face of the “U” oriented toward the water to block light pollution from the villages, beach fires, any vehicles operating on the beach after dark, or other sources of light pollution. Filter fencing requires high maintenance because it is often washed out by incoming tides, buried by winds, and/or completely uprooted by storm activity. If not properly maintained, hatchlings may become entangled in the fencing. However, since 2005 when filter fencing was first employed for all turtle nests, no occurrences of hatchlings becoming entangled in fencing have been recorded (NPS 2007e, 2008a, 2009c). Although it does not eliminate light impacts completely, the installation of filter fencing would provide long-term moderate to major beneficial impacts to sea turtles.

If it is determined that expanding the buffer around a nest prior to hatching would disrupt ORV access along the beach, the Seashore staff would immediately determine if an alternate route is available or if a reasonable bypass route could be established during the hatch window. The use of bypasses or alternate routes around sea turtle nests would protect the nests and hatchlings by diverting recreation-users away from the sensitive area and result in long-term minor beneficial impacts. Relocation of nests solely to resolve recreational access issues would not be considered.

In accordance with NCWRC guidelines, relocation for environmental reasons would be considered as a last resort since relocation carries the risk of either damaging the eggs or the embryonic development process. When a nest is found, under alternative A, staff would assess the need to relocate the nest away from areas prone to erosion or frequent flooding. If relocation is necessary, procedures for relocating nests provided in the NCWRC handbook (NCWRC 2006) would continue to be followed. Relocating nests would have both beneficial and adverse impacts. Historically, the single greatest impact on hatching success has been weather-related events, such as hurricanes or other storms, which can uncover nests through erosion, frequently flood and inundate nests, or bury nests under feet of sand (NPS 2009c, 2008a, 2007e, 2005c, 2004d, 2003e, 2002c, 2001c, 2000b). Relocating nests prone to these events to areas higher on the beach increases the likelihood that these nests would not be lost, resulting in long-term moderate to major beneficial impacts. However, relocation does have some negative impacts that would result in long-term minor to moderate adverse impacts. Six hours after deposition, the egg embryo becomes attached to the top of the eggshell. After this time, the embryo becomes very sensitive to movement and can be dislodged if the egg is rotated. This would result in the death of the embryo. In addition, relocating nests higher on the beach could alter the natural sex ratio of the nest by altering the incubation temperature. Temperatures warmer than 84.6°F produce more females, while colder temperatures produce more males. Because North Carolina is near the northern limit of loggerhead nesting, it is believed that North Carolina contributes more males to the population (Mrosofsky 1988). However, there are currently not enough temperature or sex ratio data to determine if sex ratios are being altered due to relocation efforts.

Sea turtles would continue to experience long-term minor benefits from periodic night patrols by law enforcement for the purpose of enforcing compliance with regulations and closures. Night patrol rangers have been known to place make-shift fencing around nests to protect them until turtle observers arrive in the morning (Meekins pers. comm. 2005). However, night patrols would be conducted using ORVs and could contribute to the number of false crawls that exist at the Seashore, resulting in long-term minor to moderate adverse impacts (see discussion of night driving and false crawls below under “ORV and Other Recreational Use”).

Under alternative A, the Seashore would use turtle-friendly lighting for all Seashore structures and would continue to encourage all concessionaires to install turtle-friendly lighting as well. These actions would provide long-term minor benefits to sea turtles by reducing the amount of light pollution on the beaches that could disorient emerging hatchlings or cause nesting females to abort their nesting attempts.

Under alternative A, the public would continue to receive information at the visitor centers about nesting sea turtles and the measures the Seashore is taking to protect the nests and hatchlings. The public would also continue to be notified about temporary closures that would limit ORV traffic, as well as when the closures are removed. Such public outreach is beneficial to the species because it educates the public about the specific needs of the species and alerts the public ahead of time to areas where they cannot drive due to potential impacts to the species. Therefore, public outreach under alternative A would have long-term minor beneficial impacts.

To help better understand the biology of sea turtles under alternative A, the Seashore would support research efforts studying the sex ratio of sea turtles at the Seashore. Depending upon the methodology used in conducting the research, there could be a slight risk of disturbing or injuring hatchlings or eggs. However, Seashore staff would take precautions to minimize disturbance, and information obtained from the research would be beneficial in making long-term decisions regarding nest relocation policies. Overall, sea turtle research would have long-term minor beneficial impacts.

Overall, resources management activities under alternative A would have long-term moderate benefits due to the protection provided to sea turtles.

### **ORV and Other Recreational Use**

Under alternative A, the Seashore would continue to provide sea turtles with protection from human disturbance, although there would be no restriction on night driving. Although all of the species management actions would provide some measure of protection to sea turtles, there would still be a risk of disturbance or injury to adult nesting females, hatchlings, and live stranded sea turtles due to ORV use and other activities (i.e., pedestrian use, pets). Sea turtles nest along all of the Seashore ocean beaches. Although the process of nest site selection is not well understood, and there is a lack of data describing the characteristics of nesting sites at the Seashore, 24-hour-per-day ORV use may affect the beach profile and substrate characteristics in a way that reduces suitability for nesting and hatching success (Cohen et al. 2010). Vehicle traffic on beaches contributes to erosion, especially during high tides or on narrow beaches, where driving is concentrated higher on the beach, which may make some areas unsuitable for nesting (NMFS and USFWS 2008). Vehicle driving also compacts the sand, making it more difficult for females to dig their nest cavities. Although the ORV corridor protects some of the beach from ORV use, the protected area is fairly narrow, and it is unknown if the protected areas are more suitable for nesting than the unprotected areas, or what percentage of historical nests are located within the protected area as compared to unprotected areas. Vehicles also leave ruts in the sand, and although these ruts would be raked smooth approximately 50 to 55 days into the incubation period when nest closures are expanded, closure violations do occur, leaving ruts, which can trap hatchlings attempting to reach the ocean (Hosier et al. 1981). Over the years, closure violations and vandalism of closures and nests has continued to occur (NPS 2009c, 2008a, 2007e, 2005c, 2004d, 2003e, 2002c, 2001c, 2000b), and with no increase in law enforcement or resource staffing levels under alternative A, the closure violations and vandalism would be expected to continue. Under alternative A, ORVs would have long-term minor to moderate adverse impacts because of these potential disturbances.

Recreational driving, commercial fishing vehicles, and beach fires would continue to be allowed at night within the Seashore under alternative A, resulting in long-term moderate to major adverse impacts. The presence of ORVs on the beach at night during the sea turtle nesting season could have adverse impacts

by disrupting the nesting process and causing nesting attempts to be aborted. Because visibility is reduced at night, there is also the potential for nesting, live stranded, or hatchling turtles to be hit by ORVs operating at night (NMFS and USFWS 1993; Cohen et al. 2010). Cape Hatteras and Cape Lookout national seashores are listed in the USFWS Loggerhead Recovery Plan as the only federal agencies within the nesting range allowing nighttime driving on beaches. Though actual vehicle counts are scant, patrol rangers noted substantial vehicle driving on the beaches at night in 2005 when there were no night-driving restrictions (Henson pers. comm. 2005). Night driving and heavy pedestrian use at night may also obscure turtle crawls prior to the morning turtle patrol, causing the Seashore staff to miss a turtle nest and therefore not protect it (NPS 2007e, 2004d, 2003e). Impacts to unprotected nests would be the same as discussed above under “Resources Management Activities,” resulting in long-term major adverse impacts.

False crawls (aborted turtle crawls that do not result in a nest, also often referred to as non-nesting crawls) can be detrimental to sea turtles and can be caused by, among other things, suboptimal sand conditions; encounters with roots, debris, or rocks while digging a nest; encounters with obstacles while crawling up a beach; disturbance from lights, noise, or other unusual activities; or other reasons that are not known. If too many false crawls occur for one individual, turtles can shed their eggs in the water and, thus, those eggs would be lost. Although turtles may attempt to nest again that same night or on subsequent nights, causing a turtle to abort a nesting attempt is considered an incidental take under Section 7 of the ESA, and it may cause the turtle to nest in another location that is less optimal.

Under normal, undisturbed conditions, there is generally a one to one ratio between the number of nests and the number of false crawls in a given area (Godfrey pers. comm. 2005a). Based on numbers contained in the 2000–2008 sea turtle annual reports provided by the Seashore, since 2000, an average of 49.1% of all turtle activity at the Seashore each year was false crawls, with individual years ranging from 35.5% to as high as 64.5%. Although it is not known how many false crawls have been caused directly by ORVs, specific incidents have been documented where it was known that an ORV caused the false crawl (NPS 2006e). However, it is important to note that many different factors can contribute to false crawls, and no definitive assessment exists of how the level of ORV use, or any other recreational use, may influence sea turtle nesting activity. For example, within areas open to ORV use on Hatteras Island during 2008, false crawls made up 47.5% of the total known nesting activity (19 false crawls versus 21 nests) (NPS 2009c).

The sea-finding mechanisms in emerging hatchlings are complex and involve cues from both brightness and shape. However, studies indicate that strong brightness stimuli can override competing cues (Witherington and Martin 1996). Hatchlings tend to orient toward the brightest direction over a broad horizontal direction, which on an undeveloped beach is often toward the open horizon of the ocean. However, light pollution, such as that from ORV headlights, beach fires, or lights from nearby residences or other developments, can cause emerging hatchlings to become disoriented (meander or circle) or misoriented (led in the wrong direction). Depending on the location of the artificial lights with respect to a hatching nest, hatchlings may move toward the artificial light in a direction that is away from or parallel to the ocean. This can result in the hatchlings never finding their way to the ocean. It can also cause the hatchlings to expend more energy than necessary to find the ocean, leading to exhaustion and an increased risk of predation or desiccation. Installing light filter fencing approximately 50 to 55 days into the incubation period decreases this impact somewhat by helping to shelter the emerging hatchlings from light emanating from ORV headlights, beach fires, or nearby development, but it does not eliminate the impact completely.

Beach fires are also associated with the presence of ORVs and nighttime use at the Seashore (Meekins pers. comm. 2005). As a result, both adult nesting turtles and hatchlings would be subject to long-term moderate to major adverse impacts associated with light pollution from beach fires. In 2006, a turtle crawl was discovered going into the coals of a beach fire (NPS 2007e), and in 2007, a nest was discovered two

feet from a beach fire. In this instance, visitors relayed to Seashore staff that they extinguished the fire when they saw an adult turtle crawling towards the fire (NPS 2008a). In 2008, hatchlings emerging from a nest crawled approximately 984 feet (300 meters) into a campfire to the south of the nest (NPS 2009c).

Overall, ORV and other recreational use under alternative A would result in long-term major adverse impacts to sea turtles due to the amount of Seashore available for ORV use and the lack of night-driving restrictions.

**Cumulative Impacts.** Other past, present, and future planned actions within and around the Seashore have the potential to impact the population of all three species of sea turtles that nest at the Seashore. Past storms such as hurricanes and other weather events during the turtle nesting and hatching season (April–November) have substantially impacted turtle nesting success within the Seashore and throughout the state of North Carolina and would continue to have long-term moderate to major adverse impacts. Storms, depending upon their intensity, can result in partial or complete nest loss due to flooding of nests, exposing nests due to erosion, or burying nests under feet of sand. Sea turtles have developed nesting strategies (e.g., laying lots of eggs and nesting several times during a season) to compensate for catastrophic natural events. Storms also have altered the beachscape in both positive and negative manners. In some areas, storms cause beach erosion, which has made those areas less optimal for nesting, while in other areas, storms have caused sand accretions that creates new nesting habitat. Weather events such as cold fronts can also cause sudden drops in ocean and soundside water temperatures that can cause hypothermia, which can kill sea turtles. Hurricanes can also indirectly affect sea turtles because of their impact on staff resources. Recovery efforts that detract staff from surveying/monitoring activities during sea turtle nesting and hatchling season can have long-term minor adverse impacts by causing nests to be missed due to inability to survey.

The dredging of the federally authorized navigation channel at Oregon Inlet and disposing of material on Pea Island has occurred in the past and would continue to occur on an annual basis in the future with long-term minor to moderate adverse impacts. Dredging is typically done by hydraulic pipeline dredge with work generally performed during the fall and winter months (USACE 2002). Maintenance of the navigation channels with pipeline dredges should not affect turtle species because pipeline dredges are not known to take sea turtles. Hopper dredging, which is known to take sea turtles, is currently performed under a Regional Biological Opinion (RBO) issued by the NMFS for hopper dredging in the southeastern United States. All provisions of this RBO, or any issued subsequently, are strictly followed. No sea turtles have ever been taken by hopper dredges at Oregon Inlet, and under the recommended plan, the use of a hopper dredge to construct and maintain the navigation channel would be extremely rare (USACE 2002). Nests laid in the area are currently relocated by Refuge personnel because of the severely eroded nature of some beach areas and the possibility of nest overwash by high tides. However, because encroachment into the nesting season during dredging and disposal events could occasionally occur, and because of the possibility of missing a sea turtle nest during the nest surveys or inadvertently breaking eggs during relocation, it has been determined that the recommended project may affect both the loggerhead and green sea turtles that nest on Pea Island (USACE 2002). Dredging occurs during the turtle nesting season, and occasionally a hopper dredge is used, which has been known to be responsible for incidental takes of sea turtles. Heavy construction equipment may also be used during the deposition of the dredged material, which is typically placed on Pea Island. Heavy equipment use could lead to increased erosion or soil compaction, making the habitat less suitable for nesting.

Berm construction under the CCC provided dune stabilization that changed the habitat available to sea turtles at the Seashore. These stabilization efforts provided for the establishment of NC-12 and subsequent development, removing this area from potential habitat. These stabilization efforts also altered the natural morphology and ecology of the dunes and beaches within the Seashore and have contributed to the narrowing of the beaches through erosion (Cohen et al. 2010). These past actions resulted in long-term

moderate adverse impacts to all sea turtle species at the Seashore. Similar to the original efforts of the CCC, the widening of NC-12 (on Bodie Island) and continued berm maintenance would continue to result in long-term moderate adverse impacts to sea turtles by continuing to contribute to the narrowing of the beaches through erosion.

Several of the local and NPS past, current, and future planning efforts can also affect sea turtle species. For example, new development that has occurred in Dare and Hyde counties under their land use plans had increased the residential housing and related services in the areas within the Seashore. This land development within the Seashore, as well as throughout the coastal portions of the counties, has reduced the amount and quality of habitat available to turtle species, resulting in adverse impacts. In addition to past actions, new development could result from the implementation of the County Land Use Development Plans for Dare and Hyde counties, including expected revisions to the Dare County Plan.

Although the details are lacking, additional development within the Seashore's boundaries that may result from implementing the land use plan may have long-term minor to moderate adverse impacts by increasing the amount of light pollution on the beaches causing adult turtles to abort nesting attempts and hatchlings to be disoriented when trying to make their way to the sea. Development might also increase the recreational use of the beaches and the impacts that recreation has on sea turtles.

The educational aspect of the Seashore's Long-range Interpretive Plan would provide long-term minor benefits to the sea turtles because it would help to educate visitors about the sea turtles that inhabit the Seashore and the protection measures that are put in place to help protect them. The Predator Management Plan would also provide long-term minor benefits to the sea turtles by helping to control mammalian predators, such as fox and raccoon, which prey upon sea turtle eggs and hatchlings. However, there could be a slight chance that predator trapping would result in disturbance to females or hatchlings, or result in nest or hatchling loss if trappers are not cognizant of nest locations, resulting in long-term minor to moderate adverse impacts.

The Cape Lookout National Park Interim Protected Species Management Plan/EA provides long-term moderate beneficial impacts to all three species of nesting sea turtles at the Seashore through the management policies that it employs. However, even with those management measures in place, adverse impacts would still occur to the species as recreational uses, including night driving, would still occur, but would be mitigated to an extent by the management measures being employed such as frequent surveys for nests. The outcome of the Cape Lookout National Seashore ORV Management Plan/EIS would also have direct long-term impacts on the nesting sea turtle populations within the Seashore, as well as within the state of North Carolina. Specifically, it would have an impact on the state's goal of achieving 2,000 loggerhead nests annually within the state per the Loggerhead Recovery Plan (NMFS and USFWS 2008). However, whether the impact of the ORV plan would be beneficial or adverse to sea turtles would depend upon the management decisions that are made and ultimately implemented.

During the replacement of the Herbert C. Bonner Bridge, construction noise and lighting may adversely impact nesting females, and dredging in Pamlico Sound could impact waterborne turtles, resulting in long-term minor to moderate adverse impacts. The presence of shading from the bridge and pilings driven into the substrate may also alter the optimal suitability of the beach surrounding the bridge for turtle nesting. However, the new bridge would also provide some long-term minor benefits by allowing barrier island processes to occur more naturally than with the present bridge. The new bridge would allow the natural formation of new habitats such as overwash fans, new inlets, and low sloping beaches that could provide suitable habitat for nesting turtles. The EIS for this project found that the proposed replacement of the Bonner Bridge, and subsequent phases of elevating portions of NC-12 onto bridges is not likely to jeopardize the continued existence of listed sea turtles (FHWA 2007).

The overall cumulative impact of these past, current, and future actions—added to the effects of actions under alternative A—would result in long-term moderate to major adverse cumulative impacts.

**Conclusion.** Through the protection of adult and hatchling sea turtles, surveys and management activities would provide long-term moderate beneficial impacts. Because alternative A lacks night-driving restrictions during sea turtle breeding season, adult turtles may be killed or caused to abort nesting attempts, nests may be run over or disturbed, and hatchlings may be run over or disoriented by light pollution from vehicles and associated activities, such as recreational and commercial fishing. Therefore, ORV and other recreational use occurring under alternative A would have long-term major adverse impacts.

Past, present, and future activities both inside the Seashore and within the state of North Carolina—when combined with the impacts of ORV use and level of resource management expected under this alternative would continue to result in long-term moderate to major adverse cumulative impacts.

### Impairment Determination

*Brief Description of the Condition of the Resource.* The Seashore staff has been consistently monitoring for sea turtle nests since 1987. The number of nests recorded at the Seashore from 2000 to 2010 has fluctuated greatly, with only 43 nests recorded in 2004 and 153 nests recorded in 2010, which was the highest number on record (NPS 2010a; Muiznieks pers. comm. 2010b). Of the three species that nest at the Seashore, the loggerhead turtle is by far the most numerous, comprising approximately 95% of the known nests between 2000 and 2010 (NPS 2005c, 2007e, 2008a; 2009c; 2010a; Baker pers. comm. 2009a; Muiznieks pers. comm. 2010c). Green turtles and leatherbacks breed primarily in the tropics, with only small numbers nesting at higher latitudes. Green turtles have nested regularly at Cape Hatteras, but in fewer numbers, comprising only about 5% of the nests between 2000 and 2010, while leatherback turtles have nested infrequently at the Seashore, comprising only about 1% of the nests (NPS 2005c, 2007e, 2008a; 2009c; 2010a; Baker pers. comm. 2009a; Muiznieks pers. comm. 2010b). The vast majority of sea turtle nests occur on Hatteras and Ocracoke islands, with turtles occasionally nesting on Bodie Island (NPS 2000b, 2001c, 2002c, 2003e, 2005c, 2006e, 2007e, 2008a, 2009c, 2010a). The three species of sea turtles found at the Seashore are federally listed as threatened or endangered.

*Sea turtles are necessary to fulfill the purposes for which the Seashore was established.* The Seashore's enabling legislation provides for the Seashore to be permanently reserved as a primitive wilderness and the unique flora and fauna and physiographic conditions prevailing in the area to be preserved. The three species of sea turtles found within the Seashore are federally listed as threatened or endangered and comprise the unique flora and fauna that the Seashore was established to preserve.

*Sea turtles are key to the natural or cultural integrity of the Seashore or to the opportunity for enjoyment of the Seashore.* The threatened and endangered species that exist within the Seashore are part of the Seashore's significance. The three species of sea turtles found in the Seashore are federally listed as threatened or endangered and preservation of these species are part of why the Seashore was established (preservation of the unique flora and fauna) which is key to the natural integrity of the Seashore.

*Sea turtles are implicitly but not explicitly identified as a significant resource in the Seashore's planning documents.* The Seashore's planning documents do not provide an explicit listing of "significant resources," i.e., a list stating which resources are significant and which are not. However, the planning documents repeatedly address the flora and fauna and physiographic conditions of the Seashore, particularly migratory birds and threatened and endangered species. Sea turtles are one of the predominant threatened and endangered species found at the Seashore. Therefore it seems reasonable to conclude that the Seashore's planning documents implicitly consider sea turtles "significant" because they

are an important part of the fauna the Seashore is mandated to preserve. The Seashore's 2007 Long-Range Interpretive Plan in its description of the Seashore's purpose calls out preserving and protecting the "park's natural resources" and "dynamic barrier islands that are shaped by ongoing natural processes" (Seashore's Long-Range Interpretive Plan (NPS 2007d)). The Seashore's 2006 – 2011 Strategic Plan lists preserving and protecting the "dynamic coastal barrier island system...flora and fauna that are found in a variety of habitats at the park," including "migratory birds and several threatened and endangered species" (2006 – 2011 Strategic Plan (NPS 2007b)). The Seashore's General Management Plan states: "The overall planning objective for the national seashore is to preserve the cultural resources and the flora, fauna, and natural physiographic condition, while providing for appropriate recreational use and public access to the Oceanside and soundside shores in a manner that will minimize visitor use conflict, enhance visitor safety, and preserve park resources" (NPS 1984). The primary resource management objective of the Seashore as expressed in the General Management Plan, is to preserve the dynamic physiography and the characteristic ecological communities of the Outer Banks, in all units of the Seashore except for the developed areas.

The Seashore's Strategic Plan states "The purpose of Cape Hatteras National Seashore is to preserve and protect significant segments of barrier island coastline for the benefit and enjoyment of the people and to provide for recreational visitor use consistent with that purpose." The Seashore's Strategic Plan describes the significance of the Seashore as follows:

This dynamic coastal barrier island system continually changes in response to natural forces of wind and wave. The flora and fauna that are found in a variety of habitats at the park include migratory birds and several threatened and endangered species.

In addition to these broader planning documents that provide management for the flora and fauna, migratory birds and threatened and endangered species as part of the resources of the Seashore, the Seashore's Interim Protected Species Management Strategy provides management measures specifically for sea turtles.

*Analysis.* Implementation of alternative A has the potential for impairment to sea turtles because it may result in a decrease in Seashore population levels or a failure to restore levels that are needed to maintain a sustainable population in the Seashore and meet the long-term objectives of the Loggerhead Turtle recovery plan (NMFS and USFWS 2008). Implementation of alternative A would permit year-round unrestricted night driving on the beach and would designate the ocean and inlet shoreline and existing soundside routes as designated ORV routes. Complete or partial nest loss from causes related to human activities would be expected to occur frequently for the following reasons. An undetermined number of nests may not occur due to the level of human activity and disturbance on Seashore beaches at night when turtles typically come ashore to lay nests. Unrestricted nighttime or very early morning ORV use may cover evidence of the nest so that it is not found by the morning sea turtle patrol. Undetected nests are not managed by Seashore staff. Unmanaged nests are subject to being run over by ORVs, depredation, loss due to erosion or frequent flooding, and greater risks of hatchling disorientation or misorientation from light pollution. Hatchlings from unmanaged nests may become trapped and disoriented in tire ruts or footprints, leading to an increased risk of death by predation, being run over by subsequent ORV traffic, desiccation, or exhaustion before reaching the ocean. Disoriented/misoriented hatchlings may never reach the ocean. Detected nests are protected by a symbolically fenced closure until the hatch window, however, implementation of alternative A continues law enforcement and resource staffing at a level where closure violations and vandalism of nests would be expected to continue at the same level or at an increased level as visitation increases.

Seashore staff erect light filter fencing at managed nests during the hatch window, which lessens, but does not eliminate, impacts from vehicle headlights, lanterns, beach campfires and other sources of light

pollution that result in hatchling disorientation. There are no restrictions on use of lanterns or other auxiliary light sources on the beach at night. In addition to the direct effects of ORVs on the beach at night, unrestricted night driving also increases the potential for disturbance by people and pets carried to more distant locations by vehicles. Beach fires are also associated with the presence of ORVs and nighttime use at the Seashore. Hatchlings have been disoriented by and crawled into beach fires.

In addition to the impacts to nests and hatchlings, the presence of ORVs on the beach at night can disrupt the nesting process and cause nesting attempts to be aborted. Repeated aborted nesting attempts by the same individual can lead to the eggs being shed in the water. Sea turtles nest along all of the Seashore's ocean beaches. Although management under alternative A would provide some protection to detected sea turtle nests and hatchlings, there would continue to be risk of disturbance to adult nesting females, undetected nests, hatchlings, and live stranded sea turtles due to ORV use and associated pedestrian and pet use. Reduced visibility at night increases the potential for nesting, live stranded, or hatchling turtles to be hit by ORVs operating at night. Additionally 24-hour-per-day ORV use may affect the beach profile and substrate. Vehicle driving also compacts the sand, making it more difficult for females to dig their nest cavities. Cumulative impacts from combining the effects of alternative A with effects of other past, present, and future planned actions in and around the Seashore would likely result in adverse effects that are beyond the level of disturbance or harm that would occur naturally, and may include changes in population structure and declines in local population numbers. Therefore, implementation of alternative A has the potential to impair sea turtles.

**Determination of Effect.** Under alternative A, resources management activities would result in long-term moderate benefits due to the protection provided to sea turtles from daily surveys for nests during the sea turtle nesting season (May 1 – September 15) and installing closures around each nest found, expanding the closures and installing light filter fencing around the nests during the hatch window, relocating nests from areas prone to erosion or frequent flooding, conducting periodic night patrols to enforce compliance regulations, and installing turtle friendly lighting on the Seashore.

ORV and other recreational use would have long-term major adverse impacts on sea turtles due to the amount of Seashore available for ORV use and by allowing nighttime driving on the beach. ORV and other recreational use would have impacts on sea turtles by affecting the beach profile and substrate characteristics in ways that reduce suitability for nesting and hatching success, likely continued closure violations and vandalism, and impacts caused by night driving and beach fires. Under the ESA, these impacts would result in a finding of may affect / are likely to adversely affect sea turtles because the actions would result in direct or indirect impacts to the species that are not discountable, insignificant or beneficial. Though there would be beneficial impacts from resources management activities, the actions under alternative A would also likely cause adverse effects.

## **Impacts of Alternative B: No Action—Continuation of Management under Terms of the Consent Decree**

### **Resources Management Activities**

Surveys for sea turtle nests/crawls and monitoring for evidence of hatching under alternative B and the impacts of these activities would be the same as under alternative A.

Other management activities and impacts under alternative B would be similar to alternative A with several exceptions included in this alternative that would enhance the protection of sea turtles and their habitat. As under alternative A, Seashore staff would continue to install a 30-foot (9.1-meter) by 30-foot (9.1-meter) buffer around each turtle nest found, and after approximately 50 to 55 days, when the nest is approaching its hatch window, the turtle closure would be expanded to the surf line with varying widths

based on the level and type of recreational use in the area. The widths would be the same as alternative A; however, under alternative B, full beach closures would be enacted after September 15 when a nest enters its “hatch window” (50 to 55 days). These full beach closures would be put into place to mitigate impacts to hatchlings from night driving. By protecting all of the detected turtle nests in the Seashore during the incubation and hatching periods, these buffers would provide long-term moderate to major beneficial impacts to the sea turtles.

In accordance with the consent decree, under alternative B, if a deliberate act of vandalism occurs to a resource closure, the buffers would be expanded by 164 feet (50 meters) for the first violation, 300 feet for a second violation, and 1,500 feet or more for a third violation. During 2009, two violations occurred to turtle closures that were deemed deliberate and resulted in the expansion of buffers by 164 feet (50-meters) (NPS 2009d). One violation occurred in an area open to ORVs, and the other was in an area open to pedestrians only. Expanding buffers in response to violations would be used as a deterrent to future deliberate acts of vandalism to protect turtle nests and hatchlings. Although some violations may still occur, as evidenced by the violations occurring in 2009, it is assumed that as a result of the impacts that expanded buffers would have on ORV and pedestrian use of the beaches, the number of violations in the future should decrease. Therefore, expanding buffers as a result of violation would have a long-term minor to moderate beneficial impact. These impacts would be the same prior to and after the June 2009 modifications to the consent decree.

If it is determined that expanding the buffer around a nest prior to hatching would disrupt ORV access along the beach, the Seashore staff would immediately assess if an alternate route is available or if a reasonable bypass route could be established at hatching time. The use of bypasses or alternate routes around sea turtle nests would protect the nests and hatchlings by diverting ORVs and pedestrians away from the sensitive area and result in long-term minor beneficial impacts. Relocation of nests solely to resolve recreational access issues would not be considered.

Overall, resource management activities under alternative B would have long-term moderate benefits due to the protection provided to sea turtles.

### **ORV and Other Recreational Use**

In general, management of ORV and other recreational use under alternative B would be the similar to alternative A, but would involve several changes that would result in additional protection of sea turtles and hatchlings.

ORV use on beaches can impact the beach profile and substrate characteristics in a way that may deteriorate the quality and quantity of suitable turtle nesting habitat. Under alternative B, in all locations open to ORV use that are not in front of villages, a 10-meter (30-foot) wide ORV-free zone would be created in the ocean backshore wherever there is sufficient beach width to allow an ORV corridor of at least 20 meters (60 foot) above the mean high tide line. This ORV-free corridor would protect some of the beach from ORV use and reduce impacts that may eventually alter the suitability of turtle nesting habitat. However, the area would be fairly narrow, and it is unknown if the areas to be protected are more suitable for turtle nesting than the unprotected areas, or what percentage of historical nests are located within the protected area as compared to unprotected area. Because of the relatively narrow section of beach being protected from ORV use impacts, the impacts would be long-term minor beneficial. Speed limits under alternative B would be 15 mph, unless otherwise posted, from May 15 through September 15; and 25 mph, unless otherwise posted, from September 15 to May 15. The 15 mph speed limit during the majority of the turtle nesting season is slower than the general 25 mph speed limit under alternative A (except where an ORV corridor is less than 100 feet wide when the speed limit under alternative A is 10 mph).

This slower speed limit would likely help ORV operators better see and potentially avoid turtles and hatchlings as they are driving, resulting in long-term negligible beneficial impacts.

Under alternative B, all potential sea turtle nesting habitat (ocean intertidal, ocean backshore, and dunes) would be closed to all nonessential ORV use, including commercial fishermen, from 10:00 p.m. until 6:00 a.m. (5:00 a.m. for commercial fishermen) from May 1 to September 15. For the period from September 16 through November 15, night driving would be allowed with a permit, although there would be no restriction on the number of permits issued. A permit could be revoked, however, for violation of applicable Seashore regulations or terms and conditions of the permit. Turtle nesting and hatching occurs mostly during nighttime hours. Only on rare occasions do these events take place during daylight hours (NPS 2005c). Therefore, prohibiting driving during the majority of the nighttime during the turtle nesting and hatching season would provide additional protection from ORV impacts, such as causing false crawls, disorienting or misorienting nesting turtles and hatchlings, running over hatchlings and/or nests, leaving behind tire ruts that can trap hatchlings, or running over turtle crawls and obscuring the tracks that help the Seashore staff identify and protect nests. While this would provide some long-term beneficial impacts to turtles, adverse impacts from night driving could still occur between the hours of sunset and 10:00 p.m.; therefore, overall, the impacts would be long-term minor to moderate adverse.

Although additional restrictions and regulations would help lessen some of the impacts from ORV and other recreational use, overall, the impacts would be long-term moderate adverse.

**Cumulative Impacts.** Cumulative impacts to sea turtles under alternative B would be very similar to those described for alternative A. Although alternative B would provide some additional protection, the adverse effects on sea turtles from other actions occurring in the region would still exist and would not be greatly offset by the additional protection afforded under alternative B. Therefore, the effects of these other actions—added to the effects of actions under alternative B—would result in long-term moderate adverse cumulative impacts.

**Conclusion.** Through early morning surveys and monitoring activities, the protection of nests and hatchling sea turtles, and restrictions on night driving during the sea turtle nesting season, alternative B would provide long-term moderate beneficial impacts. Because ORVs would be restricted between the hours of 10:00 p.m. and 6:00 a.m. during sea turtle breeding season, the chances are reduced that (1) adult turtles may be killed or caused to abort nesting attempts; (2) nests may be run over or disturbed; and (3) hatchlings may be killed or disoriented by light pollution from vehicles and associated recreational activities. ORV and other recreational use occurring under alternative B would have long-term moderate adverse impacts. Past, present, and future activities both inside the Seashore and within the state of North Carolina—when combined with the impacts of surveys and management activities, ORV use, and other recreational activities expected under this alternative—would continue to result in long-term moderate adverse cumulative impacts.

**Determination of Effect.** Under alternative B, resources management activities would result in long-term moderate benefits due to the protection provided to sea turtles from daily surveys for nests during the sea turtle nesting season (May 1 – September 15) and installation of closures around each nest found, expanding the closures and installing light filter fencing around the nests during the hatch window, relocating nests from areas prone to erosion or frequent flooding, and installing turtle friendly lighting on the Seashore.

ORV and other recreational use would have long-term moderate adverse impacts on sea turtles by affecting the beach profile and substrate characteristics in ways that reduce suitability for nesting and hatching success and likely continued closure violations and vandalism. While there would still be some impacts caused by night driving, these impacts would be lessened by prohibiting night driving between

the hours of 10:00 p.m. and 6:00 a.m. (5:00 a.m. for commercial fisherman) from May 1 to September 15 and requiring night-driving permits from September 16 through November 15. Under the ESA, these impacts would result in a finding of may affect / are likely to adversely affect sea turtles because the actions would result in direct or indirect impacts to the species that are not discountable, insignificant or beneficial. Though there would be beneficial impacts from resources management activities and restrictions on nonessential ORV nighttime driving, the actions under alternative B would also likely cause adverse effects.

## **Impacts of Alternative C: Seasonal Management**

### **Resources Management Activities**

Under alternative C, the Seashore staff would begin surveying the entire park daily for turtle crawls and nests on May 1 and continue until September 15 or 2 weeks after the last sea turtle nest or crawl is found, whichever is later. Surveys would be conducted in the morning using ATVs/UTVs and possibly ORVs prior to the onset of heavy public ORV use. Similar to alternatives A and B, the daily monitoring period would encompass the nesting season for the loggerhead sea turtle (mid-May to mid-August), the most prevalent nester at the Seashore, and the vast majority of the green and leatherback sea turtles' nesting seasons. Prior to May 1, the leatherback is the only species likely to nest at the Seashore, and their nests are often detected by the Seashore staff conducting bird monitoring, which would begin March 15. If a leatherback turtle nest has been reported in the state of North Carolina prior to May 1, the Seashore would follow the direction of NCWRC regarding the start of turtle patrols. From the date that daily monitoring ends to November 15, periodic monitoring (e.g., every two to three days) for nesting and emerging hatchlings would continue.

Conducting daily and periodic surveys for turtle crawls and nests during these time frames would provide long-term minor to moderate beneficial impacts because similar to alternatives A and B, they would allow nests to be identified for protection; closure violation and damage caused by ORVs or pedestrians would be detected and repaired in a timely manner and an assessment made as to whether or not any damage was done directly to a nest; tracks left behind by ORVs and/or pedestrians that are detected would be raked smooth in expanded closures; predator activity would be detected and nests protected with predator exclosures as necessary; and during periods following severe storm events or when large quantities of seaweed are washed ashore, monitoring for post-hatchling washbacks would help protect them from being run over by vehicles, disturbance from pedestrians or their pets, and potential predation. Precautions would be taken by Seashore staff to avoid potential impacts to sea turtles as described under alternative A.

Under alternative C, turtle nest closures would be the same as for alternatives A and B with 30-foot (9.1-meter) by 30-foot (9.1-meter) closures around each turtle nest found. This closure would help protect nests from being run over by ORVs or disturbed by pedestrians and/or their pets, and against erosion impacts caused by multiple ORV passes. After approximately 50 to 55 days, the turtle closure would be expanded to the surf line, with varying widths based on the level and type of recreational use in the area. In VFAs with little or no pedestrian traffic, the total width would be 75 feet (22.9 meters); on village beaches or other areas with high levels of pedestrian and other non-ORV use, the total width would be 150 feet (45.7 meters); and in ORV traffic areas the total width would be 350 feet (106.7 meters). Additionally, the closed area on the landward side of the nest would be expanded from 30 feet (9.1 meters) to 50 feet (15.2 meters). A difference under alternative C from alternatives A and B is that if multiple nests are located near each other (within 150 feet [45.7 meters]) and have similar hatch dates (within 14 days of each other), the closures would encompass all nests and would not be removed until all nests within the closure have hatched. By protecting all of the detected turtle nests in the Seashore during the incubation and hatching periods, these buffers would provide long-term moderate to major beneficial impacts to the sea turtles.

Similar to alternatives A and B, when a nest is found under alternative C, Seashore staff would determine if the nest should be relocated out of areas that are prone to erosion or frequent flooding. If relocation is necessary, procedures for relocating nests provided in the NCWRC handbook (NCWRC 2006) would be followed. A difference under alternative C from alternatives A and B is that prior to the turtle nesting season, areas in the Seashore deemed unsuitable for turtle nests (i.e., high erosion areas) would be identified by April 15, with maps and descriptions of the areas analyzed by NCWRC. This process would expedite decisions about relocating nests, which would be beneficial in making sure that all morning survey activities are completed in a timely manner. As indicated under alternative A, relocating nests results in long-term moderate to major beneficial impacts by increasing the likelihood that the nests will hatch successfully instead of being lost to storm or erosion related events. However, similar to alternatives A and B, relocating nests does have some adverse impacts including possibly altering the natural sex ratio of the nest by altering the incubation temperature, killing the embryo by dislodging it during movement, or potentially decreasing the successful hatch rate of the nest by improperly constructing the nest pit. These negative impacts would result in long-term minor to moderate adverse impacts.

Similar to alternatives A and B, as nests near their hatching date, the Seashore staff would install U-shaped light filter fencing around the nests, with the open face of the “U” oriented toward the water, to block light pollution from the villages, beach fires, any vehicles operating on the beach after dark, or other sources of light pollution. Although it would not eliminate light impacts completely, installing filter fencing would provide long-term moderate to major beneficial impacts to sea turtles.

Under alternative C, by May 1, 2012, the Seashore would install turtle friendly lighting fixtures on all the Seashore structures visible from the ocean beach except where prevented by overriding lighting requirements, such as lighthouses and fishing piers operated by NPS concessionaires. These actions would provide long-term minor benefits to sea turtles by reducing the amount of light pollution on the beaches that could disorient emerging hatchlings or cause nesting females to abort their nesting attempts. The Seashore would also work with the USFWS, the NCWRC, and Dare County to encourage the development of a turtle friendly lighting educational program or a turtle friendly lighting ordinance for villages within the Seashore on Hatteras Island. If the Seashore is able to work with these agencies to enact a turtle friendly educational program or lighting ordinance in the villages, this would result in long-term moderate to major beneficial impacts because lighting on beaches from the villages may deter turtles from coming ashore and nesting on beaches of their first choice, forcing them to lay eggs at a less optimal site. In addition, hatchlings can become disoriented by the lights and move inland toward the villages and away from the beach, resulting in mortality (NPS 2008a, 2009c).

Besides management activities targeted toward turtles, management activities targeted toward birds and seabeach amaranth under alternative C at the Seashore would also protect turtles and their nesting habitat because their habitats overlap in areas seaward of the primary dune line. Under alternative C, through the establishment of SMAs for birds and seabeach amaranth, combined with other areas that would be closed to ORVs use such as the village beaches, would close approximately 40 miles of beach to ORV use from March 15 to October 14, which encompasses the turtle nesting season. Although some of these closed areas are not historically popular turtle nesting sites (e.g., Bodie Island Spit), other areas such as Cape Point are. Closing approximately 40 miles of beach to ORV use during this period would minimize potential impacts to sea turtles and would result in long-term moderate to major beneficial impacts. The extent of the benefits would depend on the location and size of the closures, which would be reevaluated and re-designated every five years or after major hurricanes.

Under alternative C, and similar to alternatives A and B, the public would continue to receive information at the visitor centers about nesting sea turtles and the measures the Seashore is taking to protect nests and hatchlings. The public would also be notified about temporary closures that would limit ORV traffic, as

well as when these closures reopen. Such public outreach is beneficial to sea turtles because it educates the public on the specific needs of the species and alerts the public ahead of time to areas where they can and cannot go due to potential impacts to species. Similar to alternatives A and B, this aspect of public education would have a long-term minor beneficial impact. In addition, under alternative C, ORV users would be required to obtain an annual ORV users permit valid for 12 months from the date of purchase. To obtain the permit, an ORV user would need to complete a short educational program and pass a basic knowledge test showing that the person understands the rules and regulations governing ORV use at the Seashore. The permit may be revoked for violation of applicable Seashore regulations or terms and conditions of the permit. This educational requirement, with the potential deterrent of losing driving privileges on the Seashore, would have an additional long-term minor to moderate beneficial impacts, with the extent of the impacts based on the ability to enforce the regulations and apprehend violators.

To help better understand the biology of sea turtles or improve resource protection within the Seashore, under alternative C, the Seashore may authorize qualified researchers associated with recognized academic or research institutions to conduct additional scientific research on turtle species. Depending upon the methodology used in conducting the research, there could be a slight risk of disturbing, injuring, killing, or destroying turtles, hatchlings, or eggs. However, the information obtained from the research would be beneficial to the long-term survivability of the individual sea turtle species and in making long-term decisions regarding their protection within the Seashore and in other areas. Research would provide long-term minor to moderate beneficial impacts to nesting sea turtles at the Seashore.

Overall, resource management activities under alternative C would have long-term moderate to major beneficial impacts due to the added protection provided to sea turtles.

### **ORV and Other Recreational Use**

Under alternative C, the overall impact on sea turtles due to ORV use would be substantially reduced when compared to the no-action alternatives by closing approximately 40 miles of beach to ORV use during the nesting season and by closing ORV routes in potential sea turtle nesting habitat (ocean intertidal zone, ocean backshore, and dunes) to nonessential recreational ORV use from 7:00 p.m. to 7:00 a.m. between the dates of May 1 and November 15.

As described under alternative A, vehicle traffic on beaches contributes to erosion, which may eventually deteriorate the quality and quantity of nesting habitat, especially during high tides or on narrow beaches where driving is concentrated higher up on the beach. Vehicle traffic also compacts the sand, making it more difficult for females to dig their nest cavities, forcing them to expend more energy, or even causing them to abort the nesting attempt. Under alternative C, these impacts would be eliminated in some areas by closing approximately 13 miles of beach year-round (approximately 27 miles closed during the nesting season only), although not all of this area is necessarily optimal nesting habitat.

Vehicles also leave ruts in the sand and pedestrians leave footprints, and although these ruts and footprints would be raked smooth approximately 50 to 55 days into the incubation period when nests closures are expanded, closure violations do occur, leaving ruts and footprints that can trap hatchlings attempting to reach the ocean (Hosier et al. 1981; NPS 2007e, 2008a, 2009c). However, with increased education through an ORV permit program and the threat of having the permit revoked as a result of violating the Seashore's rules and regulations, it is assumed that the number of violations occurring under alternative C would decrease. While the existing level of impacts from ORVs would be expected to decrease under alternative C because there would still be adverse impacts, the above impacts from ORV use would have long-term minor to moderate adverse impacts.

As described under alternative A, turtle nesting and hatching occurs mostly during nighttime hours, and this activity can be impacted by ORVs through disorientation by light or direct mortality (NPS 2005c, 2008a). Prohibiting nonessential recreational ORV nighttime driving during turtle nesting season would virtually eliminate these potential impacts, creating long-term moderate to major beneficial impacts. However, some risk of long-term minor adverse impacts would still exist from the use of essential vehicles at night, as well as allowing night driving in area outside of existing resource closures by commercial fishermen who are actively engaged in authorized commercial fishing activities.

As described under alternative A, both nesting turtles and hatchlings are impacted by light pollution from beach fires, and many beach fires are associated with the presence of ORVs (Meekins pers. comm. 2005). Although beach fires would not be prohibited under alternative C, prohibiting ORV use during nighttime hours would likely greatly reduce the number of beach fires that occur at the Seashore, providing long-term minor to moderate beneficial impacts. Without nonessential ORV use at night, any beach fires would likely be limited to those areas in front of the villages to which people can more easily carry firewood. Even though the ability to have beach fires would require a non-fee educational permit, allowing these beach fires could impact (misorientation, disorientation, injury, and death) nesting turtles and hatchlings, resulting in long-term minor to moderate adverse impacts.

Under alternative C, portable lanterns, auxiliary lights, and powered fixed lights of any kind shining for more than 5 minutes at a time would be prohibited on the Seashore's ocean beaches. This would help eliminate point sources of light that provide additional light pollution on the beaches and minimize impacts to turtles and hatchlings, resulting in long-term minor to moderate beneficial impacts.

Restrictions placed on nonessential, recreational ORV use under alternative C would provide substantial long-term benefits to sea turtles, including seasonal night-driving restrictions that close the beach before dark (7:00 p.m.), some adverse impacts would still occur in areas where their use is allowed. Therefore, overall, ORV and other recreational use would have long-term minor adverse impacts.

**Cumulative Impacts.** Cumulative impacts to sea turtles under alternative C would be very similar to those described for alternative A. Although alternative C would provide additional protection that would be beneficial to the regional sea turtle population, the adverse effects on sea turtles from other actions occurring in the region would still exist. Therefore, the overall cumulative impact of these past, current, and futures actions—added to the effects of actions under alternative C—would result in long-term minor to moderate adverse cumulative impacts.

**Conclusion.** Through surveys and monitoring activities, the protection of nests and hatchling sea turtles, restrictions on night driving during the sea turtle nesting season, and limiting of ORVs to designated use areas, alternative C would provide long-term moderate to major beneficial impacts. Because ORV use would be restricted between the hours of 7:00 p.m. and 7:00 a.m. during sea turtle nesting season, the chances are reduced that (1) adult turtles may be killed or caused to abort nesting attempts; (2) nests may be run over or disturbed; and (3) hatchlings may be killed or disoriented by light pollution from vehicles and associated recreational activities. ORV and other recreational uses occurring under alternative C would have long-term minor adverse impacts.

Past, present, and future activities both inside the Seashore and within the state of North Carolina—when combined with the impacts of ORV use, surveys and management of species expected under this alternative—would continue to result in long-term minor to moderate adverse cumulative impacts.

**Determination of Effect.** Under alternative C, resources management activities would result in long-term moderate to major benefits due to the protection provided to sea turtles from daily surveying for nests during the sea turtle nesting season (May 1 – September 15) and installing closures around each nest found, expanding the closures and installing light filter fencing around the nests during the hatching window, relocating nests from areas prone to erosion or frequent flooding, installing turtle friendly lighting on the Seashore and working with the USFWS, NCWRC and Dare County to encourage the development of a turtle friendly lighting educational program or a turtle friendly lighting ordinance. Establishing SMAs for birds and seabeach amaranth, combined with other areas that would be closed to ORV use such as the village beaches, would close approximately 40 miles of beach to ORV use from March 15 through October 14. These closures would minimize the potential for impacts to nesting turtles, turtle nests, and turtle hatchlings in these areas.

ORV and other recreational use would have long-term minor adverse impacts on sea turtles by affecting the beach profile and substrate characteristics in ways that reduce suitability for nesting and hatching success and likely continued closure violations and vandalism. Prohibiting nonessential recreational ORV nighttime driving from 7:00 p.m. to 7:00 a.m. between the dates of May 1 and November 15 would virtually eliminate potential impacts to adult and hatchling turtles caused by night driving. Beach fires would still be allowed, and though they would likely only occur in front of the villages due to the night-driving restrictions, they would still cause adverse impacts to turtles through light pollution. Under the ESA, these impacts would result in a finding of may affect / are likely to adversely affect sea turtles because the actions would result in direct or indirect impacts to the species that are not discountable, insignificant or beneficial. Though there would be beneficial impacts from resources management activities and the prohibition on nonessential recreational ORV nighttime driving during the turtle nesting season, the actions under alternative C would also likely cause adverse effects.

## **Impacts of Alternative D: Increased Predictability and Simplified Management**

### **Resources Management Activities**

Surveying activities for sea turtles under alternative D would be the same as under alternative C, resulting in long-term minor to moderate beneficial impacts.

Other management activities for sea turtles under alternative D would be the same as under alternative C with one exception that would enhance the protection of the sea turtle habitat. Under alternative D, SMAs for bird species and seabeach amaranth would be designated as VFAs year-round, instead of just seasonally from March 15 through October 14 as under alternative C, and would be managed under ML1 procedures during the breeding season. This, along with all village beaches being designated as vehicle free year-round, would protect approximately 40 miles of the Seashore beach habitat from ORVs year-round. Prohibiting ORV use in these areas for the additional time from October 15 through March 14 would protect this habitat from additional erosion and sand compaction impacts that could eventually deteriorate the quality and quantity of turtle nesting habitat in these areas, resulting in long-term moderate to major beneficial impacts. The extent of the impact would depend on the location and size of the SMAs, which would be reevaluated and re-designated every five years, or after major hurricanes.

Overall, similar to alternative C, management activities under alternative D would result in long-term moderate to major beneficial impacts.

### **ORV and Other Recreational Use**

Impacts under alternative D would be similar to those under alternative C, with the overall impact on sea turtles lessened due to the closure of approximately 40 miles of the Seashore beach to ORV use year-

round. As under alternative C, alternative D would close ORV routes in potential sea turtle nesting habitat to recreational ORV use from 7:00 p.m. to 7:00 a.m. between the dates of May 1 and November 15.

While restrictions placed on ORV use under alternative D would provide long-term moderate to major beneficial impacts, similar to alternative C, there would still be some level of adverse impact to sea turtles in areas where ORV use and beach fires are allowed; therefore, overall impacts from ORV and other recreational use would be long-term minor adverse.

**Cumulative Impacts.** Cumulative impacts to sea turtles under alternative D would be very similar to those described for alternative A. Although alternative D would provide additional protection that would be beneficial to the regional sea turtle population, the adverse effects on sea turtles from other actions occurring in the region would still exist. Therefore, the overall cumulative impact of these past, current, and futures actions—added to the effects of actions under alternative D—would result in long-term minor adverse cumulative impacts.

**Conclusion.** Through the protection of adult and hatchling sea turtles, surveys and management activities, limiting ORVs to designated use areas, and restricting night driving therein during the sea turtle nesting season, alternative D would provide long-term moderate to major beneficial impacts. Because beach driving would be prohibited in designated ORV use areas between 7:00 p.m. and 7:00 a.m. during the sea turtle nesting season, the chances are greatly reduced that (1) adult turtles may be killed or caused to abort nesting attempts; (2) nests may be run over or disturbed; and (3) hatchlings may be killed or disoriented by light pollution from vehicles and associated recreational activities. Year-round ORV closures in SMAs would reduce erosion and compaction of beaches in these areas, providing benefits to sea turtle habitat. ORV activities occurring under alternative D would have long-term minor adverse impacts.

Past, present, and future activities both inside the Seashore and within the state of North Carolina—when combined with the impacts of ORV use, surveys and management of species expected under this alternative would have long-term minor adverse cumulative impacts.

**Determination of Effect.** Under alternative D, resources management activities would result in long-term moderate to major benefits due to the protection provided to sea turtles from daily surveying for nests during the sea turtle nesting season (May 1 – September 15) and installation of closures around each nest found, expanding the closures and installing light filter fencing around the nests during the hatch window, relocating nests from areas prone to erosion or frequent flooding, installing turtle friendly lighting on the Seashore and working with the USFWS, the NCWRC and Dare County to encourage the development of a turtle friendly lighting educational program or a turtle friendly lighting ordinance. Establishing SMAs for birds and seabeach amaranth, combined with other areas such as the village beaches that would be designated as vehicle free, would close approximately 40 miles of Seashore beach to ORV use year-round. These closures would minimize potential impacts to nesting turtles, turtle nests, and turtle hatchlings in these areas.

ORV and other recreational use would have long-term minor adverse impacts on sea turtles by affecting the beach profile and substrate characteristics in ways that reduce suitability for nesting and hatching success and likely continued closure violations and vandalism. Prohibiting recreational ORV use from 7:00 p.m. to 7:00 a.m. between the dates of May 1 and November 15 would virtually eliminate potential impacts to adult and hatchling turtles caused by night driving. Beach fires would still be allowed, and though they would likely only occur in front of the villages due to the night-driving restrictions, they would still cause adverse impacts to turtles through light pollution. Under the ESA, these impacts would result in a finding of may affect / are likely to adversely affect to sea turtles because the actions would result in direct or indirect impacts to the species that are not discountable, insignificant or beneficial. Though there would be beneficial impacts from resources management activities and the prohibition on

recreational night driving during the turtle nesting season, the actions under alternative D would also likely cause adverse effects.

## **Impacts of Alternative E: Variable Access and Maximum Management**

### **Resources Management Activities**

Surveying activities for sea turtles under alternative E would be the same as under alternatives C and D, resulting in long-term minor to moderate beneficial impacts.

Other management activities for sea turtles under alternative E would be the same as under alternatives C and D with the exception that SMAs would be closed to ORV use for 5.5 months from March 15 through August 31, and SMAs under ML2 procedures at Bodie Island Spit, Cape Point, and South Point would have ORV pass-through corridors, subject to resource closures. While not all closed areas are necessarily historically popular nesting sites, the SMAs, combined with other areas that would be closed to ORV use such as the village beaches, would protect approximately 36 miles of the Seashore from ORV use during the majority of the sea turtle nesting season and provide long-term moderate to major beneficial impacts. The extent of the impact would depend on the location and size of the closures, which would be reevaluated and redesigned every 5 years or after major hurricanes. The beneficial impacts in SMAs under ML2 procedures would be tempered slightly with pass-through corridors subject to potential deterioration of nesting habitat due to the compaction of sand and contributing factors to erosion that result from ORV use. While SMAs would reopen after August 31, this would have only negligible to minor adverse impacts directly on nesting sea turtles, because since 1998, there has been minimal nesting activity at the Seashore after August 31, with only two nests and no false crawls recorded (NPS 2006e, 2007e, 2008a, 2009c).

Management activities would provide long-term moderate to major beneficial impacts to sea turtles.

### **ORV and Other Recreational Use**

The majority of impacts under alternative E would be the same as those under alternatives C and D with the following exceptions, due to differences in night-driving restrictions and provisions for overnight ORV use via a park-and-stay option.

Under alternative E, designated ORV routes in potential sea turtle nesting habitat (ocean intertidal zone, ocean backshore, and dunes) would be closed to nonessential ORV use from 10:00 p.m. to 6:00 a.m. from May 1 through November 15. For the period from September 16 through November 15, ORV routes with no or a low density of turtle nests would reopen to ORV use between 10:00 p.m. and 6:00 a.m., subject to terms and conditions of a permit. Turtle nesting and hatching occurs mostly during nighttime hours. Only on rare occasions do these events take place during daylight hours (NPS 2005c). Therefore, prohibiting driving during the majority of the nighttime during the turtle nesting and hatching season would provide additional protection from ORV impacts such as causing false crawls, misorienting or disorienting nesting turtles and hatchlings, running over hatchlings and/or nests, leaving behind tire ruts that can trap hatchlings, or running over turtle crawls and obscuring the tracks that help Seashore staff identify and protect nests. Although this would provide some long-term beneficial impacts to turtles, adverse impacts from night driving could still occur between the hours of sunset and 10:00 p.m. Additionally, in those areas reopened to ORV use at night after September 15, hatchlings would be subjected to nighttime impacts from ORVs, but the potential for adverse impacts would be reduced by limiting it to areas where there are no nests or a very low density of nests. Therefore, while some beneficial impacts from limiting night driving would occur, night-driving impacts under alternative E would be long-term minor to

moderate adverse. These impacts would be less than alternatives A and B, but more than alternatives C and D.

In addition, allowing night driving until 10:00 p.m. would likely increase the number of beach fires that occur throughout the Seashore as compared to alternatives C and D because the ability to easily carry firewood would not be restricted to areas in front of the villages. Therefore, impacts from light pollution resulting from beach fires would be more widespread under alternative E, similar to alternatives A and B, resulting in long-term minor to moderate adverse impacts.

Under alternative E, a limited number of ORVs would be allowed to park-and-stay overnight with a permit at selected spits and points, if not otherwise closed to protect resources. Fifteen vehicles would be allowed to stay at each inlet spit, while 25 vehicles would be allowed to stay overnight at Cape Point and South Point. Limitations on night-driving and lighting restrictions (i.e., portable lanterns, auxiliary lights, and powered fixed lights of any kind shining for more than 5 minutes at a time would be prohibited, similar to all action alternatives) would help limit the amount of impacts created by these park-and-stay vehicles; however, they would still pose potential obstacles to turtles coming ashore to nest, possibly causing false crawls and turtles to expend more energy to find another nesting location that may be less optimal. This would result in long-term minor adverse impacts.

Under alternative E, a 10-meter (30-foot) wide ORV-free zone would be designated in the ocean backshore wherever there was sufficient beach width to allow an ORV corridor of at least 30 meters (90 feet) above the mean high tide line. This ORV-free zone would protect some turtle nesting habitat from ORV use; however, the area is fairly narrow, and it is unknown if the areas to be protected are more suitable for turtle nesting than the unprotected areas, or what percentage of historic nests are located within the protected area as compared to unprotected area. Because of the relative narrow portion of habitat protected, the impacts would be long-term minor beneficial.

While additional restrictions and regulations would help lessen some of the impacts from ORV use and other recreational activities, overall, the impacts would be long-term moderate adverse from allowing night driving until 10:00 p.m., and due to increased recreational access throughout the Seashore during the turtle nesting season, including a park-and-stay option for ORVs at selected points and spits.

**Cumulative Impacts.** Cumulative impacts to sea turtles under alternative E would be very similar to those described for alternative A. Although alternative E would provide additional protection that would be beneficial to the regional sea turtle population, the adverse effects on sea turtles from other actions occurring in the region would still exist. Therefore, the overall cumulative impact of these past, current, and futures actions—added to the effects of actions under alternative E—would result in long-term moderate adverse cumulative impacts.

**Conclusion.** Through the protection of adult and hatchling sea turtles, daily surveys and management activities, limiting ORVs to designated use areas and restricting night driving therein during the sea turtle nesting season, alternative E would provide long-term moderate to major beneficial impacts. Because ORVs would be restricted between the hours of 10:00 p.m. and 6:00 a.m. during the sea turtle nesting season, the chances are reduced that (1) adult turtles may be killed or caused to abort nesting attempts; (2) nests may be run over or disturbed; and (3) hatchlings may be killed or disoriented by light pollution from vehicles and associated recreational activities. However, the chances for impacts to turtles under alternative E would be greater than under alternatives C or D due to ORV and other recreational use allowed between sunset and 10:00 p.m. and over night under the park-and-stay provision. Therefore, the implementation of alternative E would result in long-term moderate adverse impacts to sea turtles.

Past, present, and future activities both inside the Seashore and within the state of North Carolina—when combined with the impacts of surveys and management activities, ORV use, and other recreational activities expected under this alternative—would continue to result in long-term moderate adverse cumulative impacts.

**Determination of Effect.** Under alternative E, resources management activities would result in long-term moderate to major benefits due to the protection provided to sea turtles from daily surveying for nests during the sea turtle nesting season (May 1 – September 15) and installing closures around each nest found, expanding the closures and installing light filter fencing around the nests during the hatching window, relocating nests from areas prone to erosion or frequent flooding, installing turtle friendly lighting on the Seashore and working with the USFWS, the NCWRC and Dare County to encourage the development of a turtle friendly lighting educational program or a turtle friendly lighting ordinance. The benefits of establishing SMAs for birds and seabeach amaranth closures and SMAs under ML2 procedures at Bodie Island Spit, Cape Point, and South Point, combined with other areas that would be closed to ORV use such as the village beaches, would close approximately 36 miles of Seashore beach to ORV use during the majority of the sea turtle nesting season. These closures would minimize potential impacts turtles, turtle nests, and turtle hatchlings in these areas; however, the benefits would be tempered somewhat by the fact that the SMAs would only be closed to ORV use from March 15 through August 31 which does not encompass the entire turtle nesting season and ORV pass-through corridors would be provided for the SMAs operating under ML2 procedures.

ORV and other recreational use would have long-term moderate adverse impacts resulting from some level of nighttime driving and due to increased recreational access throughout the Seashore, including a limited number of ORVs allowed overnight at selected points and spits. ORV and other recreational use would have adverse impacts on sea turtles by affecting the beach profile and substrate characteristics in ways that reduce suitability for nesting and hatching success and likely continued closure violations and vandalism. While there would still be some impacts caused by night driving, these impacts would be lessened by prohibiting night driving between the hours of 10:00 p.m. and 6:00 a.m. from May 1 to November 15. Opening select ORV routes with no or a low density of turtle nests from September 16 through November 15, subject to terms and conditions of a permit could impact turtles in those areas. Beach fires would still be allowed, and due to night driving being allowed until 10:00 p.m., beach fires would likely occur in areas throughout the Seashore besides just in front of the villages and therefore could still cause adverse impacts to adult and hatchling turtles through light pollution. Under the ESA, these impacts would result in a finding of may affect/are likely to adversely affect sea turtles because the actions would result in direct or indirect impacts to the species that are not discountable, insignificant or beneficial. Though there would be beneficial impacts from resources management activities and restrictions on nonessential recreational ORV nighttime driving, the actions under alternative E would also likely cause adverse effects.

## **Impacts of Alternative F: NPS Preferred Alternative**

### **Resources Management Activities**

Surveying activities for sea turtles under alternative F would be the same as under alternatives C, D, and E, resulting in long-term minor to moderate beneficial impacts to sea turtles.

Other species management activities for sea turtles under alternative F would be similar to alternatives C, D, and E, with the exception that SMAs would not be designated for the protection of bird and seabeach amaranth species. Instead, areas of high resource sensitivity and high visitor use would generally be designated as VFAs year-round or as seasonal ORV routes, with restrictions based on seasonal resource and visitor use, and one set of standard buffers, similar to the ML2 buffers under other action alternatives,

would be used. Also under alternative F, ORV corridors provided at Cape Point and South Point would be reduced from 50 meters (164 feet) to 35 meters (115 feet) during the shorebird breeding season, subject to resource closures, while Bodie Island Spit would be vehicle free from March 15 through September 14. Areas designated as SMAs under alternatives C, D, and E that would be designated as vehicle free under alternative F include the following segments of the Seashore:

- Ramp 27 to ramp 30
- Ramp 32.5 to ramp 34
- Ramp 38 to 1.5 miles south of ramp 38 (i.e., Haulover)
- 0.3 miles west of the hook (Cape Point) to 1.7 miles west of ramp 45
- Bone Road to Hatteras Inlet, along inlet shoreline to Spur Road
- Hatteras Inlet to (new) ramp 59.5
- Ramp 68 to 0.4 miles northeast of ramp 70 (includes Ocracoke Day Use area).

While not all areas closed to ORV use have historically received concentrated turtle nesting activity, the VFAs (approximately 26 miles of seashore), combined with other areas seasonally closed to ORV use (approximately 13 miles of seashore) would protect approximately 39 miles of the Seashore during a portion of the sea turtle nesting season. However, as with alternative C, some of the seasonally closed areas could be re-opened to ORV use after about July 31 (while sea turtle nesting is still ongoing), reducing the overall beneficial impacts that these closures would provide to turtles to long-term minor to moderate. The extent of the impacts would depend on the location and size of the seasonal closures. During the closures, the beneficial impacts in the Cape Point and South Point areas under alternative F would also be tempered slightly because in these two areas an ORV corridor seaward of the prenesting closures would be subject to potential deterioration of turtle nesting habitat due to the compaction of sand and contributing factors to erosion that result from ORV use. For nest relocation, NPS staff would follow guidance from the NCWRC handbook and USFWS Loggerhead Sea Turtle Recovery Plan, which is to allow nests to incubate at their original location if there is any reasonable likelihood of survival. Relocation of a nest would be considered only as an option of last resort. When relocation is necessary, the nest would be moved toward the dunes immediately behind the original nest location (when possible). Narrow beaches or beaches without nearby dunes (i.e., points and spits) may necessitate relocations to adjacent areas above the high tide line that are free of vegetation.

Overall, resource management activities would provide long-term moderate to major beneficial impacts to sea turtles.

### **ORV and Other Recreational Use**

The majority of impacts under alternative F would be similar to those under alternative E, except that there would be no impacts from park-and-stay vehicles under alternative F since this activity would be prohibited. In addition, greater beneficial impacts would be realized under alternative F due to the decreased hours night time driving allowed, as restrictions would begin 1 hour earlier in the evening and end 1 hour later in the morning than under alternative E.

Under alternative F, designated ORV routes in potential sea turtle nesting habitat (ocean intertidal zone, ocean backshore, and dunes) would be closed to nonessential ORV use from 9:00 p.m. until 7:00 a.m., corresponding roughly with dusk during the peak nesting months of June and July (dusk occurs between 8:00 p.m. and 9:00 p.m. during the months of May and August) and extending beyond dawn in the morning. Under alternative F, select ORV routes with no turtle nests remaining would reopen for night

driving between September 16 and November 15, subject to terms and conditions of the ORV permit. Turtle nesting and hatching occurs mostly during nighttime hours. However, on rare occasions these events do take place during daylight hours (NPS 2005c). A review of 21 years of nesting data on Casey Key in Sarasota County, Florida showed that the majority of loggerhead nesting activities occur after dusk<sup>10</sup> and before dawn<sup>11</sup> with only 1.4 percent of nesting occurring around dusk and no recorded nesting activities occurring during dawn (Welsh and Tucker 2009). A study of Masonboro Island in North Carolina found that hatchling emergence occurred mostly between 8:00 p.m. and 1:00 a.m. with some activity before and after these times (Neville et al. 1988). Prohibiting nonessential recreational ORV nighttime driving between the hours of 9:00 p.m. and 7:00 a.m. would greatly reduce the potential impacts to nesting turtles and hatchlings throughout the Seashore, creating long-term moderate to major beneficial impacts. In addition, not opening beaches to ORV use until 7:00 a.m. would generally allow Seashore staff time to survey the beach for nests prior to the onset of ORV use, reducing the possibility that crawls would be obscured by ORV tracks causing nests to be missed and therefore not protected as has occurred in the past. However, some risk of long-term minor to moderate adverse impacts would still exist from using essential vehicles at night, allowing driving on the beach prior to 9:00 p.m., and allowing beach access to vehicles operated by commercial fisherman beginning at 5:00 a.m. for those fisherman who are actively engaged in authorized commercial fishing activities.

While the night driving restrictions under alternative F would result in significant beneficial impacts, the restrictions do not encompass the entire night time period when nesting and hatching events could occur, especially hatching events prior to 9:00 p.m.; therefore, night time driving impacts under alternative F would be long-term minor to moderate adverse. These impacts would be significantly less than alternatives A, B, and E, but only slightly more than alternatives C and D.

Beach fires would not be prohibited under alternative F, but they would be prohibited year-round between the hours of 10:00 p.m. and 6:00 a.m. and would be restricted to the areas in front of Coquina Beach, Rodanthe, Waves, Salvo, Avon, Buxton, Frisco, Hatteras Village, and the Ocracoke Day Use Area during the sea turtle nesting season. Even though the ability to have beach fires would require a non-fee educational permit, allowing these beach fires could cause impacts (misorientation, disorientation, injury, and death) to nesting turtles and hatchlings, resulting in long-term minor to moderate adverse impacts; however, these impacts would not potentially be Seashore wide and would be restricted to the few areas where they would be allowed.

Similar to alternative E, under alternative F, a 10-meter (30-foot) wide ORV-free zone would be designated in the ocean backshore wherever there was sufficient beach width to allow an ORV corridor of at least 30 meters (90 feet) above the mean high tide line. However, unlike alternative E, this ORV-free zone would be a year-round closure under alternative F. This ORV-free corridor would protect some turtle nesting habitat from ORV use; however, the area is fairly narrow and it is unknown if the areas to be protected are more suitable for turtle nesting than the unprotected areas, or what percentage of historical nests are located within the protected area as compared to unprotected areas. Because of the relative narrow portion of habitat protected, the impacts would be long-term minor beneficial.

Under alternative F, ORV owners would be required to complete a short education program in person at an NPS facility in order to obtain a permit for ORV use. Vehicle owners would need to sign for their permit to acknowledge that they understand the rules and that all drivers of the permitted vehicle will abide by the rules and regulations governing ORV use at the Seashore. A violation of the rules and

---

<sup>10</sup> Dusk occurs after sunset and is the time at which the sun is 6 degrees below the horizon in the evening. At this time objects are distinguishable, but there is no longer enough light to perform any outdoor activities.

<sup>11</sup> Dawn is the time of morning at which the sun is 6 degrees below the horizon. At this time, there is enough light that objects are distinguishable and that outdoor activities can commence.

regulations by the owner or driver of the ORV could result in revocation of the vehicle permit, and the owner/permittee would not be allowed to obtain another permit for any vehicle for a specified period of time. This additional education would have long-term minor beneficial impacts.

While additional restrictions and regulations would help lessen some of the impacts from ORV and other recreational use, overall, the impacts would be long-term minor to moderate adverse, due to the earlier re-opening of prenesting closures (after shorebird breeding activity has concluded), resulting in increased recreational access throughout the Seashore during the sea turtle nesting season.

**Cumulative Impacts.** Cumulative impacts to sea turtles under alternative F would be very similar to those described for alternative A. Although alternative F would provide additional protection that would be beneficial to the regional sea turtle population, the adverse effects on sea turtles from other actions occurring in the region would still exist. Therefore, the overall cumulative impact of these past, current, and future actions—added to the effects of actions under alternative F—would result in long-term minor to moderate adverse cumulative impacts.

**Conclusion.** Through the protection of adult and hatchling sea turtles, surveys and management activities, limiting ORVs to designated use areas and restricting night driving therein during the sea turtle nesting season, alternative F would provide long-term moderate to major beneficial impacts. Because ORVs would be restricted between the hours of 9:00 p.m. to 7:00 a.m. the chances are greatly reduced that adult turtles (1) may be killed or caused to abort nesting attempts; (2) nests may be run over or disturbed; and (3) hatchlings may be killed or disoriented by light pollution from vehicles and associated recreational activities. ORV use and other recreational activities occurring under alternative F would have long-term minor to moderate adverse impacts.

Past, present, and future activities both inside the Seashore and within the state of North Carolina—when combined with the impacts of surveying and management activities, ORV use, and other recreational activities expected under this alternative—would continue to result in long-term minor to moderate adverse cumulative impacts.

**Determination of Effect.** Under alternative F, resources management activities would result in long-term moderate to major benefits due to the protection provided to sea turtles from daily surveys for nests during the sea turtle nesting season (May 1 – September 15) and installation of closures around each nest found, expanding the closures and installing light filter fencing around the nests during the hatch window, relocating nests from areas prone to erosion or frequent flooding, installing turtle friendly lighting on the Seashore and working with the USFWS, the NCWRC, and Dare County to encourage the development of a turtle friendly lighting educational program or a turtle friendly lighting ordinance. The benefits of establishing prenesting closures for birds combined with other areas that are closed to ORVs use either year-round or seasonally such as some of the village beaches and Bodie Island Spit, would close approximately 39 miles of Seashore beach to ORV use during the turtle nesting and hatching season. These closures would minimize potential impacts to nesting turtles, turtle nests and turtle hatchlings in these areas; however, the benefits would be tempered somewhat by the fact that the prenesting areas would only be closed to ORV use from March 15 through July 31, which does not encompass the entire turtle nesting season and ORV corridors would be provided seaward of the prenesting closures at Cape Point and South Point.

ORV and other recreational use would have long-term minor to moderate adverse impacts due to the earlier re-opening of prenesting closures (after shorebird breeding activity has concluded), resulting in increased recreational access throughout the Seashore during the sea turtle nesting season. ORV and other recreational use would have impacts on sea turtles by affecting the beach profile and substrate characteristics in ways that reduce suitability for nesting and hatching success and likely continued

closure violations and vandalism. Prohibiting recreational ORV use from 9:00 p.m. to 7:00 a.m., would greatly reduce potential impacts to adult and hatchling turtles caused by night driving. Opening select ORV routes from September 16 through November 15, subject to terms and conditions of a permit, only in areas where there are no turtle nests, would protect turtle hatchlings. Beach fires would still be allowed, but would be prohibited year-round between the hours of 10:00 p.m. and 6:00 a.m., and during the turtle nesting season would be restricted to areas in front of Coquina Beach and Rodanthe, Waves, Salvo, Avon, Buxton, Frisco, Hatteras Village, and the Ocracoke day use areas. While a permit would be required to have a beach fire, allowing beach fires would still cause adverse impacts to adult and hatchling turtles through light pollution. Under the ESA these impacts would result in a finding of may affect/are likely to adversely affect sea turtles because the actions would result in direct or indirect impacts to the species that are not discountable, insignificant, or beneficial. Though there would be beneficial impacts from resources management activities and restrictions on nonessential recreational ORV nighttime driving, the actions under alternative F would also likely cause adverse effects.

**TABLE 53. SUMMARY OF IMPACTS TO SEA TURTLES UNDER THE ALTERNATIVES**

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
<b>Resources Management Activities</b>					
Overall, resources management activities under alternative A would have long-term moderate benefits due to the protection provided to sea turtles.	Overall, resource management activities under alternative B would have long-term moderate benefits due to the protection provided to sea turtles.	Overall, resource management activities under alternative C would have long-term moderate to major beneficial impacts due to the added protection provided to sea turtles.	Overall, similar to alternative C, management activities under alternative D would result in long-term moderate to major beneficial impacts.	Management activities would provide long-term moderate to major beneficial impacts to sea turtles.	Overall, resource management activities would provide long-term moderate to major beneficial impacts to sea turtles.
<b>ORV And Other Recreational Use</b>					
Overall, ORV and other recreational use under alternative A would result in long-term major adverse impacts to sea turtles due to the amount of Seashore available for ORV use and the lack of night-driving restrictions.	Although additional restrictions and regulations would help lessen some of the impacts from ORV use and other recreational activities, overall, the impacts would be long-term moderate adverse.	Restrictions placed on nonessential, recreational ORV use under alternative C would provide substantial long-term benefits to sea turtles, including seasonal night-driving restrictions that close the beach before dark (7:00 p.m.), some adverse impacts would still occur in areas where their use is allowed. Therefore, overall, ORV and other recreational use would have long-term minor adverse impacts.	While restrictions placed on ORV use under alternative D would provide long-term moderate to major beneficial impacts, similar to alternative C, there would still be some level of adverse impact to sea turtles in areas where ORV use and beach fires are allowed; therefore, overall impacts from ORV and other recreational use would be long-term minor adverse.	While additional restrictions and regulations would help lessen some of the impacts from ORV use and other recreational activities, overall, the impacts would be long-term moderate adverse from allowing night driving until 10:00 p.m., and due to increased recreational access throughout the Seashore during the turtle nesting season, including a park-and-stay option for ORVs at selected points and spits.	While additional restrictions, such as prohibiting night driving from 9:00 p.m. to 7:00 a.m., and regulations would help lessen some of the impacts from ORV and other recreational use, overall, the impacts would be long-term minor to moderate adverse, due to not prohibiting night driving prior to 9:00 p.m. and the earlier re-opening of prenesting areas (after shorebird breeding activity has concluded), resulting in increased recreational access throughout the Seashore during the sea turtle nesting season.

## SEABEACH AMARANTH

### Species-Specific Methodology and Assumptions

Potential impacts to seabeach amaranth populations and habitat at the Seashore were evaluated based on the species life history, its past and present occurrence at the Seashore, as well as known effects on the species from activities relating to humans, pets, predators, and ORVs. Information about habitat and other existing data were acquired from staff at Cape Hatteras National Seashore, the USFWS, and available literature.

The analysis focuses on impacts to seabeach amaranth from a variety of human recreational and other activities, as well as impacts incurred as a result of surveying and management activities. Seabeach amaranth often grows in habitat areas used by other protected species within the Seashore such as plovers, oystercatchers, colonial waterbirds, and sea turtles. Therefore, any ORV-related closures established to protect the habitat or nests of these species would also benefit seabeach amaranth, although the extent of the benefit would depend upon the actual location, size, and duration of the closures. It is also assumed that increases in natural resource and law enforcement staffing at the Seashore would increase public compliance with closures and other Seashore regulations (e.g., leash laws) from that which currently exists.

Primary steps in assessing impacts to seabeach amaranth at the Seashore were to determine (1) occurrence and location of seabeach amaranth in areas likely to be affected by management actions described in the alternatives; (2) current and future use and distribution of ORV by alternative; (3) habitat impact or alteration caused by the alternatives; and (4) disturbance potential of the actions and the potential to directly or indirectly affect seabeach amaranth as a result of ORV use. The information contained in this analysis was obtained through best professional judgment of staff and experts in the field and by reviewing applicable scientific literature.

Seabeach amaranth is a fugitive annual, or a species adapted to inhabit newly disturbed habitats yearly, whose seeds are viable for long periods of time and can be dispersed long distances by wind and water, allowing it to occupy newly created habitat. Seeds may also just accumulate around the base of a plant when it dies, allowing it to continue to occupy currently available habitat. As an example of its fugitive nature, seabeach amaranth was extirpated in New York from Long Island's barrier beaches for 35 years prior to plants being discovered in 1990, 1991, and again in 1992 (LIBS 1992), though it is not known if this reoccurrence resulted from seed dispersal from other plant populations or exposure of local seed banks (USFWS 1996b). The plant was also found in New Jersey in 2000 after not being reported from the state since 1913; it was rediscovered in Delaware in 2000 after a 125-year absence; and in 1998, it was rediscovered in Maryland on Assateague Island after 31 years of not being reported, while on the Virginia side of Assateague Island it was rediscovered in 2001 (USFWS 2007d).

At the Seashore, seabeach amaranth populations have fluctuated greatly since surveys began in 1985; however, no plants have been found since 2005. In 2005, two plants were found—one located on Bodie Island Spit and one on Ocracoke Island. In 2004, only one plant was found; it was located on Bodie Island Spit. The area on Bodie Island Spit where the plants were located has been continuously protected through summer and winter resources management closures. At Cape Point, a portion of the area where seabeach amaranth was historically found has also been continuously protected through summer and winter resource closures. However, no plants have been found in these protected areas. Additionally, large portions of the plant's historical range at Hatteras Inlet where plants were found from 2001 to 2003 are no longer present due to continued erosion and retreat of the shoreline (NPS 2009e). While it is thought that the plant may possibly be extirpated from the Seashore (NPS 2009e), it should be noted that since plants are not evident every year, but may survive in the seed bank, populations of seabeach amaranth may still

be present even though plants are not visible for several years (USFWS 2007d). Despite the fact that seabeach amaranth has not been found in the Seashore since 2005, it is still necessary to protect potential habitat where plants might eventually occur, as well as unknown sites where seeds might be, in addition to protecting plants and currently occupied habitat (Jolls et al. 2004).

## Impact Thresholds

A summary of seabeach amaranth impacts under all alternatives is provided in table 54 at the end of this section.

The following thresholds for evaluating impacts to seabeach amaranth were defined.

- Negligible:* There would be no observable or measurable impacts to seabeach amaranth, its habitats, or the natural processes sustaining it. Impacts to the plant community would be well within natural fluctuations.
- Minor Adverse:* Impacts on seabeach amaranth would be measurable or perceptible, but would not be outside the natural range of variability and would be localized within a small area. Small changes to local population numbers, population structure, and other demographic factors might occur, but the natural function and character of the seabeach amaranth community would not be affected. Sufficient habitat in the Seashore would remain functional to maintain a sustainable population in the Seashore.
- Minor Beneficial:* Impacts on seabeach amaranth, its habitats, or the natural processes sustaining it would be detectable, but would not be outside the natural range of variability. Improvements to key characteristics of habitat and/or protection to key propagation stages in the Seashore would sustain or slightly improve existing population levels, population structure, or other factors and maintain a sustainable population in the Seashore.
- Moderate Adverse:* Impacts on seabeach amaranth, its habitats, or the natural processes sustaining it would be measurable or perceptible and could be outside the natural range of variability. A change would occur in the natural function and character of the seabeach amaranth community in terms of basic properties (e.g., abundance, distribution, quantity, and quality) but not to the extent that the basic properties of the community change. Sufficient population numbers and habitat in the Seashore would remain functional to maintain a sustainable population in the Seashore.
- Moderate Beneficial:* Impacts on seabeach amaranth, its habitats, or the natural processes sustaining it would be detectable and could be outside the natural range of variability. Changes to key characteristics of habitat in the Seashore and/or protection to key propagation stages would minimize or prevent injury to individual plants and improve the sustainability of the species in the Seashore.

*Major Adverse:* Impacts on seabeach amaranth, its habitats, or the natural processes sustaining it would be measurable or perceptible and would be expected to be outside the natural range of variability. Frequent disturbance to individual plants would be expected, with negative impacts that would result in a decrease in Seashore population levels or a failure to restore levels that are needed to maintain a sustainable population in the Seashore. Impacts would occur during critical periods of propagation and result in direct mortality or loss of habitat. Local population numbers, population structure, and other demographic factors might experience large declines.

*Major Beneficial:* Impacts on seabeach amaranth, its habitats in the Seashore, or the natural processes sustaining it during key life history stages would be detectable and would be expected to be outside the natural range of variability. Changes to key characteristics of habitat in the Seashore and/or protection to key propagation stages would substantially lessen mortality or loss of habitat and would result in notable increases in Seashore population levels.

*Duration:* Short-term effects would be up to two reproductive seasons for seabeach amaranth. Long-term effects would be anything beyond two reproductive seasons for seabeach amaranth.

## Study Area

The study area for assessment of the various alternatives is the Seashore. The study area for the cumulative impacts analysis is the state of North Carolina.

## Impacts of Alternative A: No Action—Continuation of Management under the Interim Protected Species Management Strategy

**Species Management Activities.** Under alternative A, during August, when plants are large enough to be easily detected, an annual survey would be conducted of all potential seabeach amaranth habitat to locate and document plants. When a seabeach amaranth plant is found outside of an existing closure (i.e., bird or turtle closure) staff would install a 30-foot (9.1-meter) by 30-foot (9.1-meter) closure around the plant(s) and mark it with signs to prevent trampling of the plants. The closures would not be removed until the plants have died in late autumn or early winter. Providing a closure of this size until the plant dies would provide long-term minor to moderate benefits by helping to protect plants from being run over by ORVs or trampled by people and from erosion caused by multiple passes of ORVs in high use areas.

Prior to the annual August survey, seabeach amaranth would be subject only to ancillary surveys by bird and turtle monitors while they conduct their primary duties. Seabeach amaranth seedlings are typically first visible beginning in June. With only ancillary observations being made during routine bird and turtle surveys, plants germinating outside of an established bird closure or other area where vehicles are prohibited would likely not be detected, resulting in long-term minor to moderate adverse impacts. Any plants that are not detected and subsequently protected may be destroyed by ORVs or other human activities, including Seashore staff using vehicles to conduct bird and turtle surveys. Any plants that are destroyed would not be detected and accounted for during the August survey.

Historically, most areas where seabeach amaranth has been found at the Seashore were either in established bird closures or other areas closed to vehicular traffic (NPS 2009e). The primary habitat of seabeach amaranth consists of overwash flats at accreting ends of islands and the sparsely vegetated zone

between the high tide line and the toe of the primary dune. Much of this habitat corresponds with that of piping plover, American oystercatcher, and other protected bird species at the Seashore. Therefore, when prenesting closures are installed beginning in March and then subsequently expanded to protect nesting birds and unfledged chicks, seabeach amaranth plants and those portions of its habitat that overlap with the closures would be protected during its growing season, resulting in long-term minor to moderate beneficial impacts. However, protection afforded to seabeach amaranth by closures for other protected species would vary annually and depend upon the location, size, and duration of the other species closures. Because seabeach amaranth must recruit annually and its seeds can be dispersed long distances via wind and water, closures for other species that overlap seabeach amaranth habitat and the 30-foot (9.1-meter) by 30-foot (9.1-meter) buffers installed around plants would not likely protect all areas in the Seashore where seeds exist and could potentially germinate in areas of ORV traffic. Unprotected seedlings or plants in areas open to ORV use would likely be crushed and go completely undocumented and seeds may be pulverized or buried. Because ATVs/UTVs and/or ORVs are used to conduct bird and turtle surveys and monitoring, there would also be a small probability of essential vehicle impacts on plants and seeds due to crushing and burial, respectively, causing long-term minor adverse impacts.

Under alternative A, bird and turtle closures would be surveyed for seabeach amaranth prior to reopening them to ORV traffic when the closures are no longer required to protect nesting birds and their chicks and turtle nests and hatchlings. If any plants are detected, buffers around the plants would be established while other areas of the closures where there are no plants would be reopened to ORV traffic. Areas identified as potential alternate/bypass ORV routes around bird and turtle closures would also be surveyed for seabeach amaranth, and buffers around plants would be established prior to using the routes. These actions would protect any plants and/or seeds that exist within these areas and result in long-term minor to moderate beneficial impacts.

Under alternative A, the Seashore would continue to place interpretive signs at all ORV entry points and at Seashore kiosks describing the effects and susceptibility of seabeach amaranth to pedestrian and ORV use. The Seashore would also continue to notify the public of all resource closures and openings. These actions would be beneficial for helping to protect seabeach amaranth. Therefore, outreach measures would have long-term minor beneficial impacts.

Overall, because of the protection of seabeach amaranth habitat and plants under alternative A, surveys conducted for amaranth plants and protection measures taken when plants are detected would have long-term minor to moderate beneficial impacts to amaranth habitat and plants when they occur.

**ORV and Other Recreational Use.** Under alternative A, ORV use would be restricted to a corridor 100 feet wide above the mean high tide line in breeding areas of protected bird species from April 1 to August 31. While this corridor would protect a small strip of potential seabeach amaranth habitat near the toe of the dunes, much of the corridor, especially located near and on the spits and Cape Point, would lie within primary seabeach amaranth habitat and would expose any seeds or germinating plants to direct and indirect impacts from ORVs. Stems of the plant are easily broken or crushed by foot traffic and tires; thus, even limited traffic can be detrimental during the growing season (USFWS 1993). Besides damaging plants, ORVs can also pulverize seeds and bury them to depths beyond which they can germinate. In areas of the Seashore where beach widths are greatly reduced, the 100-foot-wide corridor could encroach on the toe of the dunes, increasing the likelihood for impacting seeds and/or seedlings, resulting in long-term minor to moderate adverse impacts.

During the seabeach amaranth's dormant season (December to April), there are fewer closures for protected birds. Only those suitable interior habitats at the spits and at Cape Point used by nonbreeding and wintering piping plovers are closed year-round to ORV and pedestrian traffic. Therefore, more seabeach amaranth habitat would be open to impacts from ORV use. Although there are no plants that can

be damaged by ORVs during the plant's dormant period, ORV traffic can still have an adverse impact on seabeach amaranth by either pulverizing or burying the plant's seeds when driving over them (USFWS 1996b), resulting in long-term moderate adverse impacts.

While off-season ORV traffic can adversely affect seabeach amaranth through its impacts on seeds, it may also provide some benefits to the plant through the disturbance of perennial grasses and shrubs (USFWS 1996b). Seabeach amaranth is intolerant of competition from other plants. If left undisturbed, many areas within the Seashore would naturally progress through successional stages whereby perennial grasses and shrubs would become established, thus rendering the habitat unsuitable for seabeach amaranth. By using areas in late fall and winter that were previously closed to ORV traffic, ORV use helps prevent the establishment of perennial grasses and shrubs. Where this disturbance overlaps with potential seabeach amaranth habitat, it helps to maintain that habitat as potentially suitable for seabeach amaranth, resulting in long-term minor beneficial impacts.

Pedestrians would continue to be prohibited from seabeach amaranth closures under alternative A. Pedestrian use of beaches typically does not overlap heavily with the habitat of seabeach amaranth because joggers prefer wet sand and sunbathers prefer to be closer to the water. Pedestrian traffic during the plants' dormant season is much less than during its growing season and would not likely have any impacts on the species. Even during the growing season, pedestrian traffic would generally have little effect on seabeach amaranth populations because many beaches with daily use by thousands of sunbathers, joggers, and other recreation enthusiasts have substantial and apparently healthy populations of seabeach amaranth (USFWS 1996b). However, some undetected seedlings/plants could still be trampled by pedestrians and/or their pets, resulting in long-term minor to moderate adverse impacts.

Overall, ORV and other recreational use under alternative A would have long-term moderate adverse impacts as plants may go undetected, and would therefore be unprotected from this use.

**Cumulative Impacts.** Other past, present, and future planned actions within and around the Seashore have the potential to impact seabeach amaranth. Hurricanes and other weather events can have both long-term moderate to major adverse and beneficial impacts on seabeach amaranth within the Seashore and throughout the plant's range. Seabeach amaranth is extremely susceptible to overwash, and strong storms can cause overwash in areas even at the toe of the dunes. If a storm occurs early enough in the growing season, it can destroy plants before they set seed. Storms can also bury seeds so deep that they cannot germinate. However, storms can also uncover previously buried seed banks, bringing them back to a depth where they can then germinate. Storms also play a major role in dispersing seeds through both wind and water, and can reestablish populations in areas that had become devoid of plants. Storms can destroy habitat through erosion or create new habitat by creating overwash areas. Hurricanes can also indirectly affect seabeach amaranth because of their impact on staff resources. Hurricane recovery efforts that pull staff from resources management (and presumably surveying) activities would have long-term minor to moderate adverse impacts by causing plants to be missed and therefore go unprotected.

The dredging of the federally authorized navigation channel at Oregon Inlet has occurred in the past and major dredging events would continue to occur about every four years. The actual dredging does not directly impact seabeach amaranth; however, heavy construction equipment use at the deposition site, usually Pea Island (USACE 2002), could result in long-term minor adverse impacts by pulverizing or burying seeds or running over undetected seedlings or plants. Dredging of channels in and around barrier islands occurs throughout the seabeach amaranth's habitat in North Carolina and would have the same impact, depending upon the level of protection afforded the plant.

Berm construction under the CCC provided dune stabilization that changed the habitat available to seabeach amaranth at the Seashore. These stabilization efforts provided for the establishment of NC-12

and subsequent development, removing this area from potential habitat. These stabilization efforts also altered the natural morphology and ecology of the dunes and beaches within the Seashore and have contributed to the narrowing of the beaches through erosion and removal of newly created overwash habitat (Cohen et al. 2010). Stabilization of the dune system by planting vegetation is also detrimental to seabeach amaranth. These past actions resulted in long-term moderate adverse impacts to seabeach amaranth at the Seashore. Similar to the original efforts of the CCC, the widening of NC-12 (on Bodie Island) and continued berm maintenance would continue to result in long-term moderate adverse impacts to seabeach amaranth by continuing to contribute to the narrowing of the beaches through erosion.

Several of the local and NPS past, current, and future planning efforts can also affect the seabeach amaranth. For example, new development that has occurred in Dare and Hyde counties under their land use plans had increased the residential housing and related services in the areas within the Seashore. This land development within the Seashore, as well as throughout the counties, has reduced the amount of habitat available to seabeach amaranth, resulting in adverse impacts. In addition to past actions, new development could result from the implementation of the County Land Use Development Plans for Dare and Hyde counties, including expected revisions to the Dare County Plan. Though the details are lacking, if additional development results from implementing the land use plan, the amount of recreation on the area beaches would also likely increase, resulting in potential long-term minor to moderate adverse impacts. Other potential impacts from development are indeterminate at this time. The education aspect of the Seashore's Long-Range Interpretive Plan would provide long-term minor benefits to seabeach amaranth because it would help to educate visitors about the plant and the protection measures that are put in place at the Seashore to help protect it. Under the Predator Management Plan, there is a slight chance that trappers hunting fox and other mammalian predators would trample seabeach amaranth plants during their trapping efforts, resulting in long-term minor to moderate adverse impacts.

The Cape Lookout Interim Protected Species Management Plan/EA provides long-term moderate to major beneficial impacts to seabeach amaranth at the neighboring Seashore through the management policies that it employs. However, even with those management measures in place, adverse impacts would still occur to the species as recreational uses, including night driving, would still occur, but would be mitigated to an extent by the management measures being employed. The measures that are in place now under the interim plan increase protections, in part, by surveying for seabeach amaranth earlier in the season and by conducting surveys for the plant before shorebird and turtle closures are reopened, as noted in the Cape Lookout Interim Protected Species Management Plan/EA. The outcome of the current action to develop a Cape Lookout National Seashore ORV Management Plan/EIS could have long-term minor to moderate beneficial impacts on seabeach amaranth populations within Cape Hatteras National Seashore and throughout the rest of the plant's habitat in North Carolina. Populations of seabeach amaranth in the south are probably sources of long distance seed dispersal due to the fact that storms move northward along the U.S. Atlantic seacoast; thus, Cape Lookout National Seashore could be a potential seed source for suitable habitat in Cape Hatteras National Seashore and northward. However, whether the impacts of the long-term ORV plan would be beneficial or adverse depends upon the policies developed with regard to where within the Seashore ORVs would be allowed to go and during what time of year.

The replacement of the Herbert C. Bonner Bridge would result in both long-term minor to moderate adverse and beneficial impacts, with the EIS for this project noting that seabeach amaranth has not been found since 2004, and if suitable habitat were found, a survey for this species would be conducted. The area near the bridge is suitable habitat for seabeach amaranth as evidence by the presence of the only plant located within the Seashore in 2004. While construction activities could impact seabeach amaranth through direct disturbance of plants or the burying of seeds, surveying for plants prior to construction activities would help minimize this impact. However, the replacement of the bridge would allow the formation of ephemeral habitats to occur more naturally, including overwash fans, increasing the amount of habitat suitable for colonization by seabeach amaranth.

The overall impacts of these past, current, and future actions, in combination with the effects of alternative A, would result in long-term moderate adverse cumulative impacts to seabeach amaranth within the Cape Hatteras National Seashore and throughout the plant's habitat range in North Carolina.

**Conclusion.** Although there would be some level of impact during surveys and implementation of protection measures due to a risk of disturbing plants, use of experienced staff in areas of known occurrence or habitat would minimize this risk. Overall, species management activities would reduce potential impacts from ORV and other recreational use and would have minor to moderate beneficial impacts. Because ORV and other recreational use could result in plants being run over/trampled and seeds being pulverized or buried to a depth where they cannot germinate, alternative A would have long-term moderate adverse impacts.

Past, present, and future activities both inside the Seashore and within the plant's historic range in North Carolina, when combined with the impacts of ORVs, other recreational use, and resources management activities for this species, would result in long-term moderate adverse cumulative impacts.

**Determination of Effect.** Under alternative A, resources management activities would result in long-term minor to moderate benefits to seabeach amaranth if plants are detected in the Seashore. Benefits would be due to the protection provided by installing closures around plants that are detected, surveying for plants in August when they are visible, installing prenesting and other closures for nesting bird species that overlap seabeach amaranth habitat, and surveying bird and turtle closures for plants prior to reopening these closures to ORV and other recreation use.

ORV and other recreational use would have long-term moderate adverse impacts on seabeach amaranth as plants may go undetected and therefore unprotected from recreational use of the Seashore. While ORV use would be restricted to a corridor 100 feet wide above the mean high tide line in breeding areas of protected bird species from April 1 to August 31, much of the corridor, especially located near and on the spits and Cape Point would lie within primary seabeach amaranth habitat and would expose any seeds or germinating plants to impacts from ORV use and other recreation use. During seabeach amaranth's dormant season more areas of the Seashore are open to ORV use, and while there would be no plants to be impacted, seeds of the plant could be either pulverized or buried by ORVs driving over them. Under the ESA, these impacts would result in a finding of may affect / are likely to adversely affect seabeach amaranth because the actions would result in direct or indirect impacts to the species that are not discountable, insignificant or beneficial. Though there would be beneficial impacts from resources management activities, the actions under alternative A would also likely cause adverse effects.

## **Impacts of Alternative B: No Action—Continuation of Management under Terms of the Consent Decree**

### **Species Management Activities**

Surveys conducted for seabeach amaranth plants and protection measures implemented when plants are detected under alternative B would be the same as under alternative A, resulting in long-term minor to moderate beneficial impacts to seabeach amaranth.

Management activities under alternative B would be the same as under alternative A except for the following management changes for bird species habitat that would also benefit seabeach amaranth. Under the consent decree issued in 2008, the Seashore would establish prenesting areas on Bodie Island Spit, Cape Point, South Beach, Hatteras Inlet Spit, North Ocracoke Spit, and South Point, and these areas would not be reduced to accommodate an ORV corridor. The prenesting areas would remain in place until the later of July 15 or two weeks after the last tern, black skimmer, American oystercatcher, piping

plover, or Wilson's plover chick within the area has fledged. In subsequent years, the Seashore would establish prenesting closures that incorporate to the maximum extent possible the areas delineated in 2008. Because these areas overlap seabeach amaranth habitat, they would protect potential habitat for seabeach amaranth where it could possibly re-establish itself in the Seashore, and if it does, to potentially continue to survive at in the Seashore. The total amount of potential habitat protected each year would be dependent on the dynamic nature of the Seashore and the amount of breeding habitat used by during the previous three years since that is what the prenesting closures are based on. These prenesting closures would provide long-term moderate beneficial impacts to seabeach amaranth and would be the same as before the June 2009 amendment to the consent decree.

Additional closures for unfledged chicks would not provide a substantial benefit to seabeach amaranth, because the additional areas to be closed would have already been open to ORV and pedestrian use, and they are readily adjusted to accommodate the movement of the chicks. Therefore, they would not provide a sufficient amount of time for seabeach amaranth seeds to germinate and exist without potential impacts from ORVs and/or pedestrians. However, because these areas would still be surveyed prior to reopening them, they would provide long-term minor beneficial impacts to seabeach amaranth.

Overall, surveys conducted for seabeach amaranth plants and the protection measures implemented when plants are detected would result in long-term minor to moderate beneficial impacts. Although plants are scarce and would be difficult to detect, they would be provided protection once detected.

#### **ORV and Other Recreational Use**

Under alternative B, the impacts from ORV and other recreational use would be the same as under alternative A, except with additional measures that would slightly reduce adverse impacts to seabeach amaranth. Under alternative B, in all locations open to ORV use that are not in front of villages, a 32.8-foot (10-meter) wide ORV-free zone would be created in the ocean backshore wherever there is sufficient beach width to allow an ORV corridor of at least 65.6 feet (20 meters) above the mean high tide line. This ORV-free corridor would protect some of the beach from ORV use and reduce impacts on seabeach amaranth plants and habitat. However, the area would be fairly narrow, and it is unknown if the areas to be protected are more suitable for seabeach amaranth than the unprotected areas. Also, under alternative B, shorebird breeding closures would be larger and longer-lasting, providing some additional protection to seabeach amaranth compared to alternative A.

Overall, ORV and other recreational use would result in long-term moderate adverse impacts. Slightly more protection would be provided for the species when compared to alternative A due to shorebird breeding closures being larger and lasting longer and the establishment of backshore closures. However, plants may still go undetected, and would therefore be unprotected from recreational disturbance.

**Cumulative Impacts.** Cumulative impacts to seabeach amaranth under alternative B would be the same as those described under alternative A. Although alternative B would provide some additional benefits to the plant, the adverse effects on seabeach amaranth from other actions occurring in North Carolina would still exist and would not be greatly offset by the additional protection afforded under alternative B. Therefore, the effects of these other actions, added to the effects of actions under alternative B would result in long-term moderate adverse cumulative impacts to seabeach amaranth in the Seashore and throughout the plant's habitat range in North Carolina.

**Conclusion.** Overall surveys conducted for seabeach amaranth plants and protection measures implemented when plants are detected would reduce potential impacts from ORV and other recreational use, resulting in long-term minor to moderate beneficial impacts. Because ORV and other recreational use

could result in plants being run over/trampled and seeds being pulverized or buried to a depth where they cannot germinate, alternative B would have long-term moderate adverse impacts.

Past, present, and future activities both inside the Seashore and within the plant's historical range in North Carolina, when combined with the impacts of ORVs, other recreational use, and resources management activities for this species, would result in long-term moderate adverse cumulative impacts.

**Determination of Effect.** Under alternative B, resources management activities would result in long-term minor to moderate benefits to seabeach amaranth if plants are detected on the Seashore. Benefits would be due to the protection provided by installing closures around plants that are detected, surveying for plants in August when they are visible, installing prenesting and other closures for nesting bird species that overlap seabeach amaranth habitat, and surveying bird and turtle closures for plants prior to reopening these closures to ORV and other recreational use.

ORV and other recreational use would have long-term moderate adverse impacts on seabeach amaranth as plants may go undetected and therefore would be unprotected from recreation use of the Seashore. While ORV use would be restricted to a corridor 100 feet wide above the mean high tide line in breeding areas of protected bird species from April 1 to August 31, much of the corridor, especially located near and on the spits and Cape Point would lie within primary seabeach amaranth habitat and would expose any seeds or germinating plants. Some additional seabeach amaranth habitat would be protected in all areas open to ORV use that are not in front of villages, a 32.8-foot (10-meter) wide ORV-free zone would be created in the ocean backshore wherever there is sufficient beach width to allow an ORV corridor of at least 65.6 feet (20 meters) above the mean high tide line. During seabeach amaranth's dormant season more areas of the Seashore are open to ORV use, and while there would be no plants to be impacted, seeds of the plant could be either pulverized or buried by ORVs driving over them. Under the ESA, these impacts would result in a finding of may affect / are likely to adversely affect seabeach amaranth because the actions would result in direct or indirect impacts to the species that are not discountable, insignificant or beneficial. Though there would be beneficial impacts from resources management activities, the actions under alternative B would also likely cause adverse effects.

## **Impacts of Alternative C: Seasonal Management**

### **Species Management Activities**

Surveys conducted for seabeach amaranth plants and protection measures implemented when plants are detected under alternative C would be the same as under alternatives A and B, resulting in long-term minor to moderate beneficial impacts.

Management activities under alternative C would be the same as under alternative B, except for the following management changes that would provide additional protection of seabeach amaranth habitat.

Under alternative C, the NPS would identify suitable seabeach amaranth habitat at the spits and Cape Point where plants have been observed in more than one (i.e., two or more) of the past five years prior to June 1 and would delineate these areas with symbolic fencing by June 1 if such areas are not already protected within existing shorebird resource closure(s). The SMAs for protected species would be re-evaluated and re-designated every five years, or after major hurricanes. Though no areas would currently be protected because there have not been plants observed in two or more of the past five years, the establishment of these SMAs would protect any plants that do become established in the future and would provide long-term moderate beneficial impacts. These SMAs, however, would not be year-round closures and would be reopened to ORV and pedestrian use (as long as there are no overlapping bird or turtle

resource closures) by September 1 if no plants are present, or if plants are present, the closures would remain until the plant dies.

Additionally, SMAs for shorebirds would be established and closed to ORV use from March 15 to October 14. While there would currently be no seabeach amaranth SMAs established under alternative C for reasons stated above, the establishment of the shorebird SMAs and other year-round ORV closures would result in approximately 40 miles of beach that would be closed seasonally to ORV use. Closing this amount of beach to ORV use would minimize potential impacts to seabeach amaranth and its habitat and would result in long-term moderate beneficial impacts. Bodie Island Spit, Cape Point, and South Point would be managed under ML2 procedures and would have pedestrian access corridors, unless closed by shorebird breeding behavior buffers, which would result in some adverse impacts to seabeach amaranth, slightly reducing the overall benefits in these areas. Overall, the extent of the benefits from SMAs would depend on the location and size of the closures, which would be re-evaluated and re-designated every five years or after major hurricanes, but would be more than alternatives A and B.

In addition to public education on seabeach amaranth described under alternative A, additional information about the plant and the Seashore's rules and regulations would be provided via the ORV permit that users would need to obtain. With the threat of permit revocation if a user violates the Seashore's regulations or terms of the permit, it is assumed that greater compliance with closures would occur, resulting in additional long-term minor to moderate beneficial impacts, with the extent of the impacts based on the ability to enforce the regulations and apprehend violators.

Overall, because of the protection of seabeach amaranth habitat and plants under alternative C, resource management activities would have long-term moderate beneficial impacts to seabeach amaranth as the establishment of SMAs and increased protection for the species would occur compared to alternatives A and B.

### **ORV and Other Recreational Use**

Under alternative C, the impacts from ORV and other recreational use would be less than under alternative B due to the seasonal restrictions on ORV use at most locations where seabeach amaranth has historically been found. In addition, six new beach access ramps would be constructed. This would eliminate some potential seabeach amaranth habitat; however, the amount of habitat impacted is small when compared to the available habitat in the Seashore. Therefore, the new ramps would have long-term negligible to minor adverse impacts.

Overall, ORV and other recreational use would result in long-term minor to moderate adverse impacts. Because of the establishment of SMAs and protection of approximately 40 miles of beach from March 15 to October 14, the adverse impacts under alternative C would likely be less than those under alternative B, but exactly how much less would be dependent on the size, location, and duration of the SMA closures.

**Cumulative Impacts.** Cumulative impacts to seabeach amaranth under alternative C would be the same as those described under alternative A. Although alternative C would provide some additional benefits to the plant, the adverse effects on seabeach amaranth from other actions occurring in North Carolina would still exist and would not be greatly offset by the additional protection afforded under alternative C. Therefore, the effects of these other actions, added to the effects of actions under alternative C, would result in long-term minor to moderate adverse cumulative impacts.

**Conclusion.** Surveys conducted for seabeach amaranth plants and protection measures implemented when plants are detected would reduce potential impacts from ORV and other recreational use (i.e., pedestrian use and pets), resulting in long-term moderate beneficial impacts. Because the amount of beach

habitat seasonally protected from ORV and other recreational use under alternative C, the chance of plants being run over/trampled and seeds being pulverized or buried to a depth where they cannot germinate would be reduced, when compared to alternatives A and B. Alternative C would have long-term minor to moderate adverse impacts to seabeach amaranth.

Past, present, and future activities both inside the Seashore and within the plant's historical range in North Carolina, when combined with the impacts of ORVs, other recreational use, and resources management activities for this species, would result in long-term minor to moderate adverse cumulative impacts.

**Determination of Effect.** Under alternative C, resources management activities would result in long-term moderate benefits to seabeach amaranth if plants are detected on the Seashore. Benefits would be due to the protection provided by installing closures around plants that are detected, surveying for plants in August when they are visible, installing prenesting and other closures for nesting bird species that overlap seabeach amaranth habitat, and surveying bird and turtle closures for plants prior to reopening these closures to ORVs and other recreational uses. Additional protection would be provided by identifying suitable seabeach amaranth habitat prior to June 1 at the spits and points where plants have been observed in more than one of the past five years and protecting these areas (i.e., establish a seabeach amaranth SMA). The establishment of shorebird SMAs and other year-round ORV closures would close approximately 40 miles of Seashore beach to ORV use from March 15 to October 14, minimizing potential impacts to seabeach amaranth and its habitat in these areas.

ORV and other recreational use would have long-term minor to moderate adverse impacts on seabeach amaranth as plants may go undetected and would therefore remain unprotected from recreational disturbance. Seasonal restrictions on ORV use at most locations where seabeach amaranth has historically been found, due to seabeach amaranth and shorebird SMAs, would help protect the species from impacts in those areas during the plant's growing season. Constructing six new beach access ramps would eliminate some potential habitat for the species. During seabeach amaranth's dormant season, more areas of the Seashore are open to ORV use, and while there would be no plants to be impacted, seeds of the plant could be either pulverized or buried by ORVs driving over them. Under the ESA, these impacts would result in a finding of may affect / are likely to adversely affect seabeach amaranth because the actions would result in direct or indirect impacts to the species that are not discountable, insignificant, or beneficial. Though there would be beneficial impacts from resources management activities, the actions under alternative C would also likely cause adverse effects.

## **Impacts of Alternative D: Increased Predictability and Simplified Management**

### **Resources Management Activities**

Surveys conducted for seabeach amaranth plants and protection measures implemented when plants are detected under alternative D would be the similar to alternatives A, B, and C, but establishment of year-round SMAs would provide additional benefits as more areas would be closed to ORVs year-round and the chance of finding plants would be greater. These additional protections would result in long-term moderate to major beneficial impacts to seabeach amaranth.

Other management activities under alternative D would be the same as those under alternative C, except for the following management changes that would provide additional protection of seabeach amaranth habitat.

Under alternative D, approximately 40 miles of beach would be protected by SMAs or other ORV closures, and these closures would be year-round. Therefore, this habitat would be protected from potential adverse impacts from ORV use. Although some habitat may eventually move through some

succession stages making it unsuitable for seabeach amaranth, given the dynamic nature of the Seashore, those areas would likely be small in area compared to the overall habitat being protected. Therefore, these year-round closures would result in long-term moderate to major beneficial impacts, with the extent of the benefits dependent on the location and size of the closures.

Overall, because of the increased level of protection of seabeach amaranth habitat and plants under alternative D, when compared to other alternatives, species management actions would have long-term moderate to major beneficial impacts.

### **ORV and Other Recreational Use**

Under alternative D, the impacts from ORV and other recreational use would be less than under alternative C since ORV use would be prohibited year-round in most areas where seabeach amaranth has historically been found. In addition, four new beach access ramps would be constructed and would eliminate some potential seabeach amaranth habitat; however, the amount of habitat impacted would be small when compared to the overall available habitat in the Seashore. Therefore, the new ramps would have long-term negligible to minor adverse impacts. Overall, ORV and other recreational use would result in long-term minor adverse impacts. Because there would be approximately 40 miles of beach designated as vehicle free year-round, the adverse impacts under alternative D would be greatly reduced compared to the other alternatives and would be long-term minor adverse.

**Cumulative Impacts.** Cumulative impacts to seabeach amaranth under alternative D would be the same as those described under alternative A. Although alternative D provides significant protection of seabeach amaranth plants and habitat, the adverse effects on seabeach amaranth from other actions occurring in North Carolina would still exist. While they would be offset somewhat by the protection afforded the plant and its habitat under alternative D, the effects, when added to those under alternative D, would result in long-term minor adverse cumulative impacts.

**Conclusion.** Overall surveys conducted for seabeach amaranth plants and protection measures implemented when plants are detected would reduce potential impacts from ORV and other recreational use, resulting in long-term moderate to major beneficial impacts. Because of the amount of beach habitat protected from ORVs year-round under alternative D, the chances are greatly reduced that ORV and other recreational activities could result in plants being run over/trampled and seeds being pulverized or buried to a depth where they cannot germinate. ORV and other recreational use under alternative D would result in long-term minor adverse impacts to seabeach amaranth.

Past, present, and future activities both inside the Seashore and within the plant's historical range in North Carolina, when combined with the impacts of ORVs, other recreational use, and resources management activities for this species, would result in long-term minor adverse cumulative impacts.

**Determination of Effect.** Under alternative D, resources management activities would result in long-term moderate to major benefits to seabeach amaranth if plants are detected in the Seashore. Benefits would be due to the protection provided by installing closures around plants that are detected, surveying for plants in August when they are visible, installing prenesting and other closures for nesting bird species that overlap seabeach amaranth habitat, and surveying bird and turtle closures for plants prior to reopening these closures to ORV and other recreational use. Additional protection would be provided by identifying suitable seabeach amaranth habitat prior to June 1 at the spits and Cape Point where plants have been observed in more than one of the past five years and protecting these areas (i.e., establish a seabeach amaranth SMA). SMAs, both seabeach amaranth and shorebird, would be closed to ORVs year-round under alternative D. Combined with other year-round ORV closures, these areas would protect

approximately 40 miles of Seashore beach virtually eliminating potential impacts to seabeach amaranth and its habitat in these areas.

ORV and other recreational use would have long-term minor adverse impacts on seabeach amaranth due to reduced recreational access throughout the Seashore. Year-round restrictions on ORV use at most locations where seabeach amaranth has historically been found, due to seabeach amaranth and shorebird SMAs, would help protect the species from impacts in those areas. Constructing four new beach access ramps would eliminate some potential habitat for the species. During seabeach amaranth's dormant season some areas of the Seashore remain open to ORV use, and while there would be no plants to be impacted, seeds of the plant could be either pulverized or buried by ORVs driving over them. Under the ESA, these impacts would result in a finding of may affect / are likely to adversely affect seabeach amaranth because the actions would result in direct or indirect impacts to the species that are not discountable, insignificant or beneficial. Though there would be beneficial impacts from resources management activities, the actions under alternative D would also likely cause adverse effects.

### **Impacts of Alternative E: Variable Access and Maximum Management**

#### **Resources Management Activities**

Surveys conducted for seabeach amaranth plants and protection measures implemented when plants are detected under alternative E would be the same as under alternatives A, B, C, and D, resulting in long-term minor to moderate beneficial impacts.

Other management activities under alternative E would be the same as under alternative C, except for the following management changes that would slightly reduce the overall beneficial impacts.

Under alternative E, approximately 36 miles of beach would be protected by SMAs or other ORV closures during the breeding season. These areas would generally be closed to ORVs from March 15 to August 31, except Bodie Island Spit, Cape Point, and South Point, which would be managed under ML2 procedures and open year-round but limited to an access corridor with a pass-through zone March 15 to August 31. The access corridor may be closed depending on breeding shorebird buffers. These areas would reopen to ORV use only after the area had been thoroughly surveyed for seabeach amaranth plants in August, so any plants would not be impacted; however, suitable habitat that is reopened would be subject to impacts from ORVs and pedestrians as described under alternative A. The ORV pass-through access corridors would potentially allow some additional habitat to be impacted year-round, depending on shorebird breeding closures, but overall the closures would provide long-term moderate beneficial impacts as a result of SMA closures to ORV use from March 15 to August 31.

Overall, because of the protection provided to seabeach amaranth habitat and individual plants, alternative E would have long-term minor to moderate beneficial impacts, as three SMAs would be managed under ML2 procedures during the breeding season and more recreational access would be allowed than under action alternatives C and D.

#### **ORV and Other Recreational Use**

Under alternative E, the impacts from ORV and other recreational use would be similar to those under alternative C with the following exceptions. Under alternative E, in all locations open to ORV use that are not in front of villages, a 32.8-foot (10-meter) wide ORV-free zone would be created in the ocean backshore wherever there is sufficient beach width to allow an ORV corridor of at least 98.4 feet (30 meters) above the mean high tide line. This ORV-free corridor would protect some of the beach from ORV use and reduce impacts on seabeach amaranth plants and habitat. However, the area would be fairly

narrow and it is unknown if the areas to be protected are more suitable for seabeach amaranth than the unprotected areas. Therefore, the impacts would be long-term minor to moderate beneficial. The ORV pass-through access corridors in areas under ML2 management would allow some ORV impacts to seabeach amaranth habitat in those areas, depending on shorebird breeding closures, and would have long-term minor to moderate adverse impacts. In addition, seven new beach access ramps would be constructed throughout the Seashore. This would eliminate some potential seabeach amaranth habitat; however, the amount of habitat impacted would be small when compared to the overall available habitat on the Seashore. Therefore, the new ramps would have long-term negligible to minor adverse impacts and overall, ORV and other recreational use would have long-term minor to moderate adverse impacts to seabeach amaranth due to the increased level of recreational access allowed when compared to the other action alternatives.

**Cumulative Impacts.** Cumulative impacts to seabeach amaranth under alternative E would be the same as those described under alternative A. Although alternative E would provide some additional benefits to the plant, the adverse effects on seabeach amaranth from other actions occurring in North Carolina would still exist and would not be greatly offset by the additional protection afforded under alternative E. Therefore, the effects of these other actions, added to the effects of actions under alternative E, would result in long-term minor to moderate adverse cumulative impacts.

**Conclusion.** Overall surveys conducted for seabeach amaranth plants and protection measures implemented when plants are detected would reduce potential impacts from ORV use and other activities (i.e., pedestrian use and pets), resulting in long-term minor to moderate beneficial impacts. Because ORV and other recreational uses would be restricted in areas of known seabeach amaranth habitat, the chances would be reduced that plants could be run over/trampled and seeds being pulverized or buried to a depth where they cannot germinate. ORV and other recreational use under alternative E would result in long-term minor to moderate adverse impacts to seabeach amaranth.

Past, present, and future activities both on the Seashore and within the plant's historical range in North Carolina, when combined with the impacts of ORVs, other recreational use, and resources management activities for this species, would result in long-term minor to moderate cumulative adverse impacts.

**Determination of Effect.** Under alternative E, resources management activities would result in long-term minor to moderate benefits to seabeach amaranth if plants are detected on the Seashore. Benefits would be due to the protection provided by installing closures around plants that are detected, surveying for plants in August when they are visible, installing prenesting and other closures for nesting bird species that overlap seabeach amaranth habitat, and surveying bird and turtle closures for plants prior to reopening these closures to ORV and other recreational use. Approximately 36 miles of beach would be protected by SMAs or other ORV closures from March 15 to August 31. Bodie Island Spit, Cape Point, and South Point would be under ML2 procedures and potentially open year-round but limited to a corridor with a pass-through zone March 15 to August 31. These closures would protect seabeach amaranth and its habitat during these timeframes, but would allow ORV impacts to occur during the dormant season when these areas are reopened.

ORV and other recreational use would have long-term minor to moderate adverse impacts on seabeach amaranth as plants may go undetected and therefore unprotected from recreation use of the Seashore. Seasonal restrictions on ORV use at most locations where seabeach amaranth has historically been found, due to seabeach amaranth and shorebird SMAs, would help protect the species from impacts in those areas. Some additional seabeach amaranth habitat would be protected, for in all areas open to ORV use that are not in front of villages, a 32.8-foot (10-meter) wide ORV-free zone would be created in the ocean backshore wherever there is sufficient beach width to allow an ORV corridor of at least 98.4 feet (30 meters) above the mean high tide line. Constructing seven new beach access ramps could eliminate some

potential habitat for the species, but these areas are not known to be habitat for seabeach amaranth. During seabeach amaranth's dormant season more areas of the Seashore are open to ORV use, and while there would be no plants to be impacted, seeds of the plant could be either pulverized or buried by ORVs driving over them. Under the ESA, these impacts would result in a finding of may affect / are likely to adversely affect seabeach amaranth because the actions would result in direct or indirect impacts to the species that are not discountable, insignificant or beneficial. Though there would be beneficial impacts from resources management activities, the actions under alternative E would also likely cause adverse effects.

## **Impacts of Alternative F: NPS Preferred Alternative**

### **Resources Management Activities**

Surveys conducted for seabeach amaranth plants and protection measures implemented when plants are detected under alternative F would be the same as under all other alternatives, resulting in long-term minor-to moderate beneficial impacts.

Protection measures under alternative F would be the same as under alternative E, except for the following management changes.

Under alternative F, SMAs would not be designated for shorebird resources. However, some areas designated as SMAs under alternatives C, D, and E would be designated as year-round VFAs under alternative F and would include the following segments of the Seashore:

- Ramp 27 to ramp 30
- Ramp 32.5 to ramp 34
- Ramp 38 to 1.5 miles south of ramp 38 (i.e., Haulover)
- 0.3 miles west of the hook (Cape Point) to 1.7 miles west of ramp 45
- Bone Road to Hatteras Inlet, along inlet shoreline to Spur Road
- Hatteras Inlet to (new) ramp 59.5
- Ramp 68 to 0.4 miles northeast of ramp 70 (includes Ocracoke Day Use area).

In total, under alternative F approximately 26 miles of shoreline would be designated as year-round VFAs, approximately 13 miles would be seasonally designated for ORV use from November 1 to March 31, and approximately 26 miles would be designated for ORV use year-round; providing a total of approximately 39 miles of shoreline that would be protected at least seasonally. While not all of the areas closed to ORV use would be habitat suitable for seabeach amaranth, the areas do include the historically important seabeach amaranth habitat located from approximately 0.3 miles west of Cape Point to 1.7 miles west of ramp 45 and Bodie Island spit.

Though SMAs would not be designated for shorebirds, prenesting closures would be established as detailed in table 10-1 and would be in place from March 15 to July 31 (or August 15 if black skimmers are present) then removed if no birds are present, or two weeks after all chicks have fledged, whichever comes later. Cape Point and South Point would have an ORV access corridor that may be closed depending on breeding shorebird buffers. Though these seasonal closures could potentially reopen to ORV use prior to the annual August survey for seabeach amaranth, they would be surveyed for seabeach amaranth prior to reopening them and any plants found would be protected with 30-foot (9.1-meter) by 30-foot (9.1-meter) closures, so any plants would not be impacted. Also, an annual habitat assessment

would be conducted at the points and spits after all birds have fledged from the area. Prior to removing the prenesting closures, resource closures would be established in the most sensitive portions of nonbreeding shorebird habitat in these areas, based on habitat used by wintering piping plovers in more than one (i.e., two or more) of the past five years. These resource closures would provide extended protection for seabeach amaranth habitat. However, habitat in other areas that is reopened and suitable for seabeach amaranth would be subject to impacts from ORVs and pedestrians as described under alternative A. The ORV corridor seaward of the prenesting closures at Cape Point and South Point would also potentially allow some additional habitat to be impacted year-round, depending on shorebird breeding closures. Therefore, these closures would provide long-term moderate beneficial impacts.

Under alternative F, SMAs would also not be designated for seabeach amaranth, though prior to June 1 each year the NPS would still identify suitable seabeach amaranth habitat at the spits and points where plants have been observed within the previous 5 years and delineate these areas with symbolic fencing if the areas are not already protected within existing shorebird resource closures(s). Though no areas would currently be protected because there have not been plants observed within the past 5 years, the establishment of these habitat closures would protect any plants that do become established in the future and would provide long-term moderate beneficial impacts. These closures, however, would not be year-round closures and would be reopened to ORV and pedestrian use (as long as there are no overlapping bird or turtle resource closures) by September 1 if no plants are present, or if plants are present, the closures would remain until the plant dies.

Overall, because of the protection provided to seabeach amaranth habitat and individual plants, alternative F would have long-term minor to moderate beneficial impacts.

#### **ORV and Other Recreational Use**

Under alternative F, the impacts from ORV and other recreational use would be the similar to those under alternative E. The construction of four new beach access ramps and the relocation of two existing ramps would eliminate some potential seabeach amaranth habitat; however, the amount of habitat impacted is small when compared to the overall available habitat on the Seashore. Therefore, the new ramps would have long-term negligible to minor adverse impacts, and, overall, ORV and other recreational use would result in long-term minor to moderate adverse impacts on seabeach habitat.

**Cumulative Impacts.** Cumulative impacts to seabeach amaranth under alternative F would be the same as those described under alternative A. Although alternative F would provide some additional benefits to the plant, the adverse effects on seabeach amaranth from other actions occurring in North Carolina would still exist and would not be greatly offset by the additional protection afforded under alternative F. Therefore, the effects of these other actions, added to the effects of actions under alternative F would result in long-term minor to moderate adverse cumulative impacts.

**Conclusion.** Overall, resources management activities would reduce potential impacts from ORV and other recreational use, resulting in long-term minor to moderate beneficial impacts. Because ORV and other recreational use could result in plants being run over/trampled and seeds being pulverized or buried to a depth where they cannot germinate, alternative F would have long-term minor to moderate adverse impacts.

Past, present, and future activities both on the Seashore and within the plant's historical range in North Carolina, when combined with the impacts of ORVs, other recreational use, and resources management activities for this species, would result in long-term minor to moderate adverse cumulative impacts.

**Determination of Effect.** Under alternative F, resources management activities would result in long-term minor to moderate benefits to seabeach amaranth if plants are detected in the Seashore. Benefits would be due to the protection provided by installing closures around plants that are detected, surveying for plants in August when they are visible, installing prenesting and other closures for nesting bird species that overlap seabeach amaranth habitat, and surveying bird and turtle closures for plants prior to reopening these closures to ORV and other recreation use. Approximately 39 miles of beach would be protected by seasonal and year-round VFAs, including Bodie Island Spit. Cape Point and South Point would have an ORV corridor seaward of the prenesting closures that may be closed depending on breeding shorebird buffers. These closures would protect seabeach amaranth and its habitat during these timeframes, but the seasonal closures would allow ORV impacts to occur during the seasons when these areas are reopened.

ORV and other recreational use would have long-term minor to moderate adverse impacts on seabeach amaranth as plants may go undetected and would therefore be unprotected from recreation use of the Seashore. Seasonal restrictions on ORV use at seabeach amaranth and shorebird prenesting closures would help protect the species from impacts in those areas. Some additional seabeach amaranth habitat would be protected, for in all areas open to ORV use that are not in front of villages, a 32.8-foot (10-meter) wide ORV-free zone would be created in the ocean backshore wherever there is sufficient beach width to allow an ORV corridor of at least 98.4 feet (30 meters) above the mean high tide line. Constructing four new beach access ramps and relocating two existing ramps would eliminate some potential habitat for the species. During seabeach amaranth’s dormant season more areas of the Seashore are open to ORV use, and while there would be no plants to be impacted, seeds of the plant could be either pulverized or buried by ORVs driving over them. Under the ESA, these impacts would result in a finding of may affect / likely to adversely affect for seabeach amaranth because the actions would result in direct or indirect impacts to the species that are not discountable, insignificant or beneficial. Though there would be beneficial impacts from resources management activities, the actions under alternative F would also likely cause adverse effects.

**TABLE 54. SUMMARY OF IMPACTS TO SEABEACH AMARANTH UNDER THE ALTERNATIVES**

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
Resources Management Activities					
Overall, because of the protection of seabeach amaranth habitat and plants under alternative A, resources management actions would have long-term minor to moderate beneficial impacts, if plants are detected.	Overall, because of the protection of seabeach amaranth habitat and plants under alternative B, resources management actions would have long-term minor to moderate beneficial impacts, if plants are detected.	Overall, because of the protection of seabeach amaranth habitat and plants under alternative C, resources management actions would have long-term moderate beneficial impacts to seabeach amaranth as the establishment of SMAs and increased protection for the species would occur compared to alternatives A and B.	Overall, because of the increased level of protection of seabeach amaranth habitat and plants under alternative D, when compared to other alternatives, resources management actions would have long-term moderate to major beneficial impacts.	Overall, because of the protection of seabeach amaranth habitat and plants under alternative E, resources management actions would have long-term minor to moderate beneficial impacts as ORV access to more areas would be allowed during the germination period, than under action alternatives C and D.	Overall, because of the protection of seabeach amaranth habitat and plants under alternative F, resources management actions would have long-term minor to moderate beneficial impacts as ORV access to more areas would be allowed during the germination period, than under action alternatives C and D.

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
ORV And Other Recreational Use					
Overall, ORV and other recreational use under alternative A would have long-term moderate adverse impacts as plants may go undetected, and therefore unprotected from this use.	Overall, ORV and other recreational use would result in long-term moderate adverse impacts. Slightly more protection would be provided for the species when compared to alternative A, due to shorebird breeding closures being larger and lasting longer.	Overall, ORV and other recreational use would result in long-term minor to moderate adverse impacts. Because of the establishment of SMAs and protection of approximately 40 miles of beach, the adverse impacts under alternative C would likely be long-term minor to moderate adverse.	Overall ORV and other recreational use would result in long-term minor adverse impacts. Because the establishment of SMAs closed to ORVs year-round would protect approximately 40 miles of beach, the adverse impacts under alternative D would be greatly reduced compared to the other alternatives and result in long-term minor adverse impacts.	Overall, ORV and other recreational use would have long-term minor to moderate adverse impacts to seabeach amaranth due to the increased level of recreational access allowed when compared to the other action alternatives.	Overall, ORV and other recreational use would be similar to those under alternative E and result in long-term minor to moderate adverse impacts to seabeach amaranth.

## STATE-LISTED AND SPECIAL STATUS SPECIES

### GUIDING REGULATIONS AND POLICIES

The NPS *Management Policies 2006* state that NPS will inventory, monitor, and manage state and locally listed species in a manner similar to its treatment of federally listed species to the greatest extent possible. In addition, the NPS will inventory other native species that are of special management concern to parks (such as rare, declining, sensitive, or unique species and their habitats) and will manage them to maintain their natural distribution and abundance (NPS 2006c, sec. 4.4.2.3). As a result, the NPS is obligated to manage access to important habitat for such species. In addition, one of the Seashore's management goals is to provide protection for species that occur within the Seashore and that suffer population reductions or require special management. Therefore, an analysis of the potential impacts to state-listed species and certain Seashore sensitive species is included in this section.

### ASSUMPTIONS, METHODOLOGY, AND IMPACT THRESHOLDS

The following information was used to assess impacts on state-listed and special status species:

1. Species found in areas likely to be affected by management actions described in the alternatives.
2. Habitat loss or alteration caused by the alternatives.
3. Displacement and disturbance potential of the actions and the species' potential to be affected by the activities.

Specific methodologies that were implemented and assumptions that were made that pertained to the American oystercatcher, colonial waterbirds, Wilson's plover, and red knot are described under the relevant species impact analysis below.

Although the action alternatives involve the construction of ramps, parking areas, and interdunal roads, construction activities would occur outside of the bird breeding season, during daylight hours, and outside of any key breeding or foraging habitat. In the unlikely event that state-listed or special status species are found in a construction area, the area would be under a resource closure and no construction would occur. Therefore, impacts from construction were assumed to be negligible.

## Study Area

The study area for state-listed and special status species is defined as the Seashore for the analysis of the impacts of the alternatives and defined as the state of North Carolina for the analysis of cumulative impacts.

## Impact Thresholds

A summary of impacts to state-listed and special status species under all alternatives is provided in table 55 at the end of this section.

The following thresholds for evaluating impacts to state-listed and special status species were defined.

*Negligible:* There would be no observable or measurable impacts to state-listed/special status species, their habitats, or the natural processes sustaining them. Impacts would be well within natural fluctuations.

*Minor Adverse:* Impacts on state-listed/special status species, their habitats, or the natural processes sustaining them would be detectable, but would not be outside the natural range of variability. Occasional responses by some individuals to disturbance could be expected, but without interference to feeding, reproduction, resting, or other factors affecting population levels. Small changes to local population numbers, population structure, and other demographic factors might occur. However, some impacts might occur during critical reproduction periods for a native species, but would not result in injury or mortality. Sufficient habitat in the Seashore would remain functional to maintain a sustainable population in the Seashore.

*Moderate Adverse:* Impacts on state-listed/special status species, their habitats, or the natural processes sustaining them would be detectable and could be outside the natural range of variability. Frequent responses by some individuals to disturbance could be expected, with some negative impacts to feeding, reproduction, resting, or other factors affecting local population levels. Some impacts might occur during critical periods of reproduction or in key habitats in the Seashore and result in harassment, injury, or mortality to one or more individuals. However, sufficient population numbers and habitat in the Seashore would remain functional to maintain a sustainable population in the Seashore.

*Major Adverse:* Impacts on state-listed/special status species, their habitats, or the natural processes sustaining them would be detectable, would be expected to be outside the natural range of variability, and would be permanent. Frequent responses by some individuals to disturbance would be expected, with negative impacts to feeding, reproduction, or other factors resulting in a decrease in Seashore population levels or a failure to restore levels that are needed to maintain a sustainable population in the Seashore. Impacts would occur during critical periods of reproduction or in key habitats in the Seashore and result in direct mortality or loss of habitat. Local population numbers, population structure, and other demographic factors might experience large declines.

*Duration:* Short-term effects would be up to two breeding seasons for state-listed/special status species.

Long-term would be anything beyond two breeding seasons for state-listed/special status species.

### **Species-Specific Methodology and Assumptions**

Potential impacts on state-listed/special status species populations and habitat were evaluated based on available data on the species' past and present occurrence at the Seashore, as well as the species' association with humans, pets, predators, and ORVs. Information on habitat and other existing data were acquired from staff at the Seashore, the USFWS, and available literature. American oystercatchers, Wilson's plover, and the red knot are identified as a species of high concern by the U.S. Shorebird Conservation Plan. American oystercatchers are listed as a species of special concern in North Carolina. The colonial waterbird species addressed in this analysis are state-listed threatened and species of special concern and include the common tern, least tern, gull-billed tern, and black skimmer.

The analysis focuses on effects to state-listed and special status species from a variety of human recreational activities, as well as impacts incurred as a result of surveying and management activities.

The following assumptions were made regarding the analysis for all alternatives:

- An indirect impact from recreation use is the attraction of mammalian and bird predators to trash associated with recreation use (USFWS 1996a, 2009a). Predation continues to be a major factor affecting the reproductive success of piping plovers (Elliot-Smith and Haig 2004), as well as other shorebirds at the Seashore. The Seashore would enforce proper trash disposal and anti-wildlife feeding regulations to reduce the attraction of predators to the area under all alternatives. Nevertheless, as demonstrated by the Seashore's annual species reports, predation continues to be a threat to species success at the Seashore (see "Chapter 3: Affected Environment"). Recreational use that brings humans into areas where state-listed/sensitive species reside would continue to have indirect impacts by attracting mammalian predators, resulting in long-term moderate impacts under all alternatives as impacts could be detectable and outside the range of natural variability, but would not result in large declines in population as the Seashore takes steps to protect listed species from predation.

## **Impacts of Alternative A: No Action—Continuation of Management under the Interim Protected Species Management Strategy**

### **Resources Management Activities**

*Establishment of Prenesting Closures.* Under alternative A, specific prenesting closures would not be established for American oystercatchers, colonial waterbirds, or Wilson's plover. For American oystercatchers and colonial waterbirds, closures would be established only when a territory is established or a nest is located. Although these species would be able to utilize prenesting closures for piping plover that are in effect April 1, no specific prenesting closures for these other species would be established. The April 1 prenesting closures for piping plover would occur at the start of, rather than before, the breeding season, and would not be available to early nesting American oystercatchers; however, these areas would be available for Wilson's plover, which nest around the same time as the piping plover. For terns and black skimmers that nest at the spits, Cape Point, and South Beach in May and June, these closures would provide protection if they nest inside the closure, but there would not be prenesting protection provided to these species at many other locations, including areas that have been utilized for nesting in the past three years. Because there are no specific prenesting closures for state-listed and special status species apart from the piping plover prenesting areas, there would be overall long-term moderate adverse impacts to these species, except for minor adverse impacts for Wilson's plover, which generally would nest within the prenesting areas established for piping plover. Because red knot do not breed at the Seashore, there would be no impacts from the establishment of prenesting closures.

*Surveying and Monitoring.* Under alternative A, Seashore staff would continue to survey recent American oystercatcher breeding areas two times per week from March 15 to June 15. Surveys for colonial waterbirds would also be two times per week from May 1 to June 15. Because surveys would be restricted to recent breeding areas, surveys may not detect American oystercatchers or colonial waterbirds that establish territories in new habitat or historic nest sites. American oystercatcher and colonial waterbird nests would be observed at least three times per week. American oystercatcher broods would be observed once daily, while colonial waterbird broods would be observed at one-day to two-day intervals. Wilson's plover nests and broods would be observed incidental to piping plover monitoring. For all state-listed/special status species, when broods are mobile, more frequent observations would be provided along with enforcement presence. Monitoring would end when all chicks have fledged.

Although surveying would provide substantial benefits to the species from data collected, surveying would bring people and/or essential vehicles into direct short-term contact with state-listed/special status species and their habitat, and these activities themselves are a known risk factor (McGowan 2004; Sabine 2005; Nol and Humphrey 1994; Simons and Schulte 2008; Corbat and Bergstrom 2000; Verhulst et al. 2001). Seashore staff would use best professional judgment and take precautions to minimize disturbance during surveying; however, all state-listed/special status species are highly vulnerable to disturbance and are known to abandon habitat when they are impacted by pedestrians, vehicles, pets, and even resource managers in or near their nesting habitat (Sabine 2005; Corbat and Bergstrom 2000). Surveying would include collection of data by Seashore staff, whose presence has the potential to lead to flushing responses, which in turn could have the potential to negatively impact feeding, reproduction, resting, or other factors. Therefore, under alternative A, species surveying could likely have long-term minor adverse impacts, from the introduction of human disturbance during these activities but overall surveying would provide long-term benefits to the species as it would allow the Seashore to better manage the species. Many of the surveying and field activities would occur outside of the primary time when red knot are present at the Seashore. Therefore, any impacts to this species from surveying and field activities would be long-term negligible adverse.

*Buffer/Closure Establishment.* Management under alternative A would begin with surveying for breeding activity beginning on March 15 for American oystercatchers and May 1 for colonial waterbirds. Prenesting areas for piping plovers would be established at spits, Cape Point, and South Beach, based on an annual habitat survey. Other species would potentially use breeding habitat protected within the piping plover prenesting areas. During prenesting, a 33-meter (100-foot) wide ORV and pedestrian corridor would be established at the spits, Cape Point, and South Beach, and pedestrian access would be prohibited outside of ORV corridors including breeding areas beyond the symbolic fencing. The ORV/pedestrian corridor would be delineated with posts placed up to 33 meters (100 feet) above the high tide line. In areas of reduced corridor width (i.e., narrower than 33 meters [100 feet]), a speed limit of 10 mph would be posted. Prenesting areas would be removed if no bird activity is seen by July 15 or when the area has been abandoned for a 2-week period, whichever comes later.

Outside of the piping plover prenesting areas, closures/buffers would be activated if American oystercatchers, colonial waterbirds, or Wilson's plover establish a territory or nest(s) are located. Management of Wilson's plover would be incidental to piping plover management. Closures would be removed when areas have been abandoned for a two week period. If territorial or courting birds are observed outside of existing closures, based on bird behavior and suitable habitat, buffers would be expanded to accommodate the birds. An ORV/pedestrian corridor would be provided above the high tide line.

These closures provide buffers around courting American oystercatchers and colonial waterbirds, which would have a substantial beneficial effect if implemented in a timely manner. Yet, as stated previously, the management actions under alternative A would bring people, essential vehicles, and equipment into direct contact with state-listed/special status species and their habitat and would provide for closures only after territorial behavior or nests are observed. These activities, as with surveying, are known risk factors. American oystercatchers at the Seashore can begin courting and nesting as early as mid-February or early March and be particularly sensitive to disturbance at that time (Cohen et al. 2010). Hence, a March 15 start to management could mean that early nesting oystercatchers, especially those that establish territories outside of historic areas, would not be fully protected under alternative A.

Under alternative A, buffers/closures would be established for nesting American oystercatchers based on the adult's reaction to human disturbance. Closures would vary in size depending upon best professional judgment. When resource closures are created around nests, the ORV corridor would adjust whenever possible to allow ORV passage, and the width of ORV corridor would be reduced if necessary. For colonial waterbirds, a buffer/closure of 50 to 100 meters (164 feet to 328 feet) would be established around the nest or colony based on observed bird behavior, while maintaining the ORV/pedestrian corridor, if possible. If the buffer and the corridor overlap each other, then staff would reduce the corridor width if necessary. For both species, in areas in which the buffer zone would eliminate the ORV corridor, an alternate ORV route would be identified if available, or a bypass provided if possible. Observations and resultant management would be responsive to individuality in bird behavior when determining adequate size of closure zones around nests.

A 50- to 100-meter (150- to 300-foot) buffer zone would be established if unfledged chicks are observed, which would adjust in size as a function of chick mobility. However, observations of chick movements may not be sufficient to adjust buffers such that they ensure protecting chicks from ORV/pedestrian impact. For example, if observations are made during times of low chick mobility, buffers would adjust to 50 meters (164 feet) and result in leaving unprotected chicks that move greater than 50 meters (164 feet) at another time. An alternate ORV/pedestrian access route or bypass would be provided to open areas beyond the closure, if possible. The 33-meter (108-foot) wide ORV corridor would be reopened in recent or current nesting areas after chicks fledge. The 150-foot ORV corridor would re-established after August

31. Under alternative A, no additional buffers or closures would be provided to foraging adult state-listed/special status species.

Although establishment of buffers around nesting/fledging areas and posting of nests with symbolic fencing can provide a major deterrent to the entry of people, pets, and ORVs into their habitats, alternative A species management would continue to bring people, essential vehicles, and equipment into direct contact with the American oystercatcher and colonial waterbirds and their habitat, and these activities are known risk factors (Buckley and Buckley 1976; Erwin 1989, 1980; Cohen et al. 2010). Also since first-time breeders are even less tolerant to disturbance than are older, established breeders (Nol and Humphrey 1994), buffers for first-time breeders may not provide sufficient protection.

With the closures and buffers for nesting areas under alternative A that may not provide sufficient protection for species, management that begins after the species are known to arrive at the Seashore, lack of certain buffers such as adult foraging buffers, and the flexibility of moving the ORV corridor to enable access adjacent to nesting areas, impacts from closures/buffers under alternative A would be long-term moderate adverse, depending on the sensitivity of each species to disturbance.

*Wintering/Nonbreeding Management.* Nonbreeding surveys for American oystercatchers, Wilson's plover, and red knot would be conducted according to the NPS SECN survey protocol, with no nonbreeding surveys for colonial waterbirds. These surveying activities would have minor adverse impacts (due to human disturbance as discussed above) and long-term benefits related to the increase in knowledge about the species. Lack of nonbreeding surveys for colonial waterbirds would have long-term minor to moderate adverse impacts, as data would not be collected to assist in the determination of future management (nonbreeding) of these birds.

No nonbreeding closures would be established for state-listed/special status species, although these species could utilize the nonbreeding closures for piping plover that would include suitable interior habitats at spits and at Cape Point year-round. Being able to utilize other species closures would have some long-term benefits, as some protection is offered during this sensitive life stage. However, these closures would not be specific to the state-listed/special status species and would not include ocean beach habitat, resulting in long-term minor adverse impacts. Wilson's plover would benefit from nonbreeding closures for piping plover as they utilize similar nonbreeding habitat.

*Education/Public Outreach.* Under alternative A, the public would continue to receive information at the visitor centers about state-listed/sensitive species and their ecology and the measures the Seashore is taking to protect the species. The public would also continue to be notified about closures that would limit ORV or pedestrian traffic, as well as when these closures reopen. Such public outreach is beneficial to the species as it educates the public to the specific needs of the species and alerts the public ahead of time to areas where they cannot go due to potential impacts to the species. Therefore, public outreach as part of species management would have long-term beneficial impacts.

*Overall Impact of Resources Management Activities.* The overall impact of resources management activities (primarily resulting from the effects of surveying and field activities) for each species under alternative A would be as follows:

- American oystercatcher. Impacts would be long-term minor to moderate adverse as surveying and lack of specific prenesting closures for this species may miss early nesters. Piping plover prenesting closures, which could be utilized by this species as well, would not protect a number of American oystercatcher nest sites used in recent years. Also, buffer distances based on bird behavior may not provide adequate protection for the species.

- Colonial waterbirds. Impacts would be long-term minor to moderate adverse as no prenesting closures would be established for colonial waterbirds. Some species, such as terns and black skimmers may be able to utilize the prenesting closures established for piping plovers; however, those prenesting areas would not protect a number of colonial waterbird nest sites used in recent years. Also, buffer distances based on bird behavior may not provide adequate protection for the species.
- Wilson's plover. Impacts would be long-term minor adverse as the habitat for this species would be well surveyed during piping plover surveys and this species would be able to take advantage of management measures for piping plover as their breeding seasons and habitat requirements are similar. Also, buffer distances based on bird behavior may not provide adequate protection for the species. Some benefits may occur from incidental management of Wilson's plover during piping plover management activities, both during breeding and nonbreeding seasons.
- Red knot. Impacts to nonbreeding red knot would be long-term minor adverse as their prime foraging habitat (ocean shoreline) would not be afforded protection by nonbreeding closures, although the ability of this species to use wintering closures for piping plover at inlets and Cape Point would result in some benefit, albeit minimal. As red knot are not present at the Seashore for breeding, any impacts to this species from surveying and field activities for other species would be long-term negligible adverse.

## ORV and Other Recreational Use

*ORV and Pedestrian Access.* Under this alternative, visitors would be allowed to operate ORVs on all the ocean and inlet shoreline and on the existing soundside routes, 24 hours per day year-round, subject to temporary resource closures, seasonal ORV closures in front of the villages, and temporary ORV safety closures (see figure 2, chapter 2, alternative A and B maps).. There would be no designated VFAs, although temporary closures would occur for resource protection and safety reasons, and seasonal closures would occur in front of the villages. Alternative A would provide for closures of piping plover prenesting areas, while maintaining access to the inlets and Cape Point. The prenesting closures, as well as closures based on observations of breeding behavior, foraging, and chick movements, may benefit other species. An ORV/pedestrian corridor would be provided above the high tide line. In areas of reduced corridor width (i.e., less than 33 meters [100 feet]), traffic signs and a 10 mph speed limit would be posted. The ORV corridor would be adjusted whenever possible to allow vehicle passage. If an ORV corridor is not feasible for safety reasons or insufficient area, an alternate ORV route would be identified if possible. If there is no alternate route available, Seashore staff would consider establishing a bypass route. Seashore staff would allow management to be responsive to individuality in bird behavior when determining adequate size of closure zones. If an alternate route or bypass is not feasible, an ORV closure would be initiated. This should limit adverse impacts to state-listed/special status species, but compliance with closures may not be absolute, resulting in short-term moderate to major adverse impacts if non-compliance occurs. Recreation use under the actions defined in alternative A would bring ORVs, essential vehicles (for safety, enforcement, etc.), pedestrian, pets, and other recreational activities in close proximity to state-listed/special status species and their habitat, and these activities are all known risk factors to these species. Oystercatchers need large, undisturbed beach areas for successful nesting and they are particularly sensitive to humans, vehicles, and unleashed pets in or near their nesting habitat (Simons and Schulte 2008; Stillman and Goss-Custard 2002). Although there would be buffers and substantial rerouting, it is likely that some American oystercatchers could be disturbed during the most critical periods of reproduction and within key American oystercatcher habitat, resulting in direct mortality, abandonment, or loss of habitat. This would be especially true if closure compliance is lacking and/or if the breach of the closure occurs in the earlier life stages. Direct mortality, abandonment, and loss of habitat have and would continue to lead to some annual and seasonal declines in the oystercatcher population at the Seashore, and impacts would be long-term moderate to major adverse. Colonial

waterbirds and Wilson's plovers would be affected especially during prenesting, territory establishment, courtship and nesting phases (Cohen et al. 2010; Corbat and Bergstrom 2000), although some Wilson's plover nesting habitat would be protected within the piping plover prenesting areas. Some of these impacts could occur during critical, early stages of reproduction and within key colonial waterbird and Wilson's plover habitat and result in abandonment of nest sites or loss of otherwise suitable habitat and could result in long-term moderate to major adverse impacts.

There would be no year-round or seasonal closures specifically to protect key red knot habitat. Recreational activities that occur in the months when red knots are present on Seashore beaches have the potential to impact resting and foraging red knots, as a result of vehicle use and associated noise and presence of people and pets. Of particular concern is when these disturbance factors result in red knots being forced to fly while they are foraging. Frequent escape flights means that time spent foraging is reduced and replaced by an increase in time spent flying, resulting in the chance that birds would not be able to add the body fat they need for their long-distance migration, resulting in long-term minor to moderate adverse impacts to red knots.

As noted in chapter 3, a 3-year study on Cape Cod and Fire Island, New York (Kluft and Ginsberg 2009), found that higher ORV traffic resulted in dispersal and desiccation of the wrack line, thereby reducing the population of invertebrates in that area. Alternative A would allow for beach driving during the day outside of resource closures, with no restrictions on night driving. While the wrack within resource closures would be protected from driving, this level of access would result in long-term minor to moderate impacts to invertebrate populations (as discussed later in this chapter) as all areas outside the resource closures would be open to driving during the day and night, and therefore would reduce the food source to all of the state-listed and special status species at the Seashore that rely on this food source, resulting in long-term moderate impacts.

*Night-Driving Restrictions.* Under alternative A, there would be no limitations on night driving. American oystercatchers, Wilson's plover, and red knot are known to be active at night (Simons and Schulte 2008; Morrier and McNeil 1991; Niles et al. 2007) and would be subject to vehicular and pedestrian disturbance. This disturbance can impact their foraging behavior and has been shown to result in disorientation and even abandonment of oystercatcher chicks (Simons and Schulte 2008). Allowing night driving under alternative A would result in long-term moderate adverse impacts to birds that forage at night.

*Commercial Fishing.* Under alternative A, commercial fishing would be managed under the commercial fishing special use permit. As part of this permit, terms and conditions would be placed on the permit holder, including a prohibition on entering resource closures. All other closures (safety and seasonal) would be accessible by commercial fishing permit holders. As resource closures would be off limits to commercial fishermen, there would be long-term negligible adverse impacts to state-listed/special status species from this use.

*Permitting/Carrying Capacity Requirements.* Under alternative A, there would be no permitting or carrying capacity requirements for ORV use at the Seashore. A permitting system would provide the Seashore with a method for dealing with non-compliance, as well as providing education to ORV users regarding the importance of state-listed and special status species habitat at the Seashore. Lack of a permit system under alternative A would have long-term moderate adverse impacts. The lack of prenesting closures for these species (or other proactive protection of nesting habitat) would result in adverse impacts that would be exacerbated by the lack of a carrying capacity requirement. These conditions would result in long-term moderate adverse impacts to most state-listed/special status species that nest on Seashore beaches, as unrestricted numbers of ORVs would be allowed in recent breeding areas prior to the implementation of resource closures that would occur only after breeding activity is observed. For

American oystercatchers that regularly forage on the ocean shoreline and on the soundside outside of resource protection areas, there would be long-term moderate to major adverse impacts, as the lack of a carrying capacity would increase the possibility of greater concentrations of ORVs, thereby increasing the potential for disturbance to oystercatchers. For Wilson's plover, which typically would nest in piping plover prenesting areas, the lack of a carrying capacity would cause long-term minor adverse impacts.

*Pet/Other Recreational Activity Restrictions.* Alternative A would prohibit camping and restrict beach fires to the hours of 6:00 a.m. until midnight, and would allow pets at the Seashore year-round, in accordance with 36 CFR 2.13. The prohibition of camping and restriction of beach fires after midnight would have long-term benefits to state-listed/special status species, as disturbance from these activities would be reduced or eliminated. The presence of pets at the Seashore, including during breeding season, has the potential to impact state-listed/special status species as some visitors to the Seashore do not observe the requirement for pets to be restrained in some manner, and buffers for these species may not be adequate under alternative A. If there is little or limited compliance with pet restrictions in the areas of closures, a negative effect on the state-listed/special status species could result (USFWS 1996a). This would be mitigated by the prohibition of pets from the landward side of the posts delineating the ORV corridor at the spits and Cape Point, by the prohibition of pets within symbolic fencing around any bird closure area, and through education and outreach efforts via the Seashore field personnel and partnerships with local volunteers and organizations, but could still result in long-term minor adverse impacts, due to non-compliance and lack of appropriate buffers.

*Overall Impact of ORV and Other Recreational Use.* The overall impact of ORV and other recreational uses for each species under alternative A would be as follows:

- American oystercatcher. Impacts would be long-term moderate to major adverse as buffers that adjust frequently based on bird behavior are more subject to non-compliance. The lack of designated VFAs, a permitting system, carrying capacity, or seasonal night-driving restrictions, and allowing pets at the Seashore during breeding season would contribute to these adverse impacts.
- Colonial waterbirds. Impacts would be long-term moderate to major adverse as buffers may not be adequate to protect the species, and disturbance from recreational uses is more likely. The lack of designated VFAs, a permitting system, carrying capacity, or seasonal night-driving restrictions, and allowing pets in the vicinity of breeding birds would also contribute to adverse impacts.
- Wilson's plover. Impacts would be long-term moderate to major adverse as no specific management would be provided for this species, although they could utilize buffers and closures established for piping plover. The lack of designated VFAs, a permitting system, carrying capacity, or seasonal night-driving restrictions, and allowing pets at the Seashore during breeding season would contribute to these adverse impacts.
- Red knot. Impacts would be long-term moderate adverse as no specific management would be provided for this species especially during a key life stage of wintering. The lack of designated VFAs, a permitting system, or night-driving restrictions when red knots are at the Seashore, and allowing pets at the Seashore during the migrating/nonbreeding season would contribute to these adverse impacts. Impacts to red knots would be lower than other species as they would not be subject to impacts during their breeding cycle and their use of the Seashore corresponds to times of lower visitation.

**Cumulative Impacts.** The following cumulative assessment applies to all the state-listed / special status bird species addressed in this section of the plan/EIS, since so many of the cumulative effects applied similarly to all of these species. While these species may use the Seashore differently (nesting vs.

wintering) or arrive at the Seashore at different times, in general the below actions would occur year-round and have the potential to impact all of the state-listed/special status species to some degree. The cumulative impact of each alternative for each species references this section, but provides an assessment of all cumulative effects, including those of each individual alternative added to the impacts discussed below. The past, present, and future actions discussed under cumulative impact scenario could be expected to have a range of impact on all the state-listed / special status bird species addressed in this section of the plan/EIS.

Various dredging is occurring in the vicinity of the Seashore, such as the dredging of Oregon Inlet. These dredging activities fall under two categories: major dredging and maintenance activities. For the dredging of the federally authorized navigation channel at Oregon Inlet, major dredging occurs approximately every four to five years, with sand being deposited in areas outside the Seashore, such as on Pea Island. Major dredging of Oregon Inlet is typically avoided during the breeding season; however, maintenance dredging does occur and could result in short-term minor adverse impacts due to disturbance. When major dredging projects do occur, it is common for bird habitat at the southern end of Bodie Island Spit to slough off into the channel for a number of months after the dredging operation, which could cause short-term minor to moderate adverse effects to habitat.

Berm construction under the CCC provided dune stabilization that changed the habitat available to all shorebird species at the Seashore. These stabilization efforts provided for the establishment of NC-12 and subsequent development, removing this area from potential habitat. These past actions resulted in long-term moderate adverse impacts to all shorebird species at the Seashore. Similarly, continual maintenance of NC-12 and berm maintenance would have a short-term, minor to moderate, adverse impact to the extent that it takes place during breeding season and if maintenance results in encroachment on any nest buffers or resource closures. If encroachment occurs, it could result in habitat loss that would have short-term, minor to moderate, adverse impacts to sensitive species nesting and foraging. The degree to which this activity is negative is a function of the timing and location of the activity itself relative to bird nesting and to the degree to which the activity impacts habitat for state-listed and special status species.

Storms and other weather events during the breeding season (March – August) of locally sensitive bird species can result (depending upon storm intensity) in disturbance of nesting state-listed/special status birds or even in the washing away of nests or eggs. In addition to the timing of summer storms, storm severity is also an important variable. Powerful storms can surge high up and overwash large areas of breeding habitat including even up to the toe of the dune and beyond and result in loss of scrapes, nests, eggs, chicks and even breeding adults. Conversely, winter, late fall, and early spring storms are capable of being beneficial to state-listed / special status birds by depositing new materials and creating overwash areas and hence new nesting habitat for state-listed / special status birds or having long-term adverse impacts by eroding and removing otherwise suitable habitat. Hence, the type and level of impacts to nesting state-listed / special status birds depends on the timing and severity of storm events and whether they result in net habitat creation or destruction.

Hurricanes can also affect American oystercatchers, Wilson's plover, and colonial waterbirds because of the impact of major storms on staff resources. Storm recovery efforts that temporarily pull staff from resources management (including species monitoring or law enforcement) activities during the breeding season would have a short-term minor adverse impact. Conversely, hurricane recovery that takes place outside of the breeding season would have no or little effect. Because the hurricane season overlaps essentially the entire breeding season, the loss of staff services would have a short-term adverse impact on these birds.

Commercial fish harvesting would have a negligible impact on American oystercatchers, Wilson's plovers, and red knots because these birds do not feed on any commercially important fish. However,

American oystercatchers, Wilson's plovers, and red knots feed on some of the same prey items of fish species that may be harvested and, as such, harvest of fish may mean greater prey encounters for these bird species. In this case, commercial fishing would have a long-term negligible to minor adverse impact on American oystercatchers, Wilson's plovers, and red knots. Colonial waterbirds on the other hand, most likely feed on the young year classes of some of the fish targeted by commercial fishermen. In this case, the harvest of commercial fish would have a long-term minor adverse impact on colonial waterbirds.

Past, current, and future planning efforts can also affect locally sensitive bird species. For example, past development that has occurred in Dare and Hyde counties under their land use plans had increased the residential housing and related services in the areas within the Seashore. This land development within the Seashore, as well as throughout the counties, has reduced the amount of habitat available to species, resulting in adverse impacts. In addition to past actions, new development could result from the implementation of the County Land Use Development Plans for Dare and Hyde counties, including expected revisions to the Dare County Plan. The details of any plan revisions are not certain and the potential for impacts on these bird species is indeterminate at this time. If increased development within the Seashore's boundaries would result from the implementation of these plans, this may have minor adverse impacts on state-listed / special status species, because development might result in measurable increases in recreational beach use, with corresponding increases in recreational impacts to these species. If visitation on the Outer Banks increases greatly, this would also increase the likelihood of American oystercatcher vehicle strikes as the species flies across NC-12 from nesting sites on the ocean shoreline to forage in the Pamlico Sound. Therefore, an increase in visitation would likely result in an increased chance of conflicts between this species and ORV.

The education aspect of the Seashore's Long-Range Interpretive Plan would provide long-term benefits to state-listed / special status birds as it would help to educate visitors about the conservation needs of the birds that inhabit the Seashore and the protection measures that are put in place to help protect them.

The Seashore's Predator Management Plan would provide long-term substantial benefits by helping to control mammalian predators, such as fox and others, which prey upon bird adults, eggs, and young. Predator trapping might result in short-term minor disturbance to nests and young, or result in loss of nests or hatchlings if trappers are not cognizant of nest locations. However, overall predator management actions would be highly beneficial to state-listed or special status bird species.

The Cape Lookout Interim Protected Species Management Plan/EA provides beneficial impacts to all state-listed/special status birds at the Seashore through the management policies that it employs. However, even with those management measures in place, adverse impacts would still occur to the species as recreational uses, including night driving, would still occur, but would be mitigated to an extent by the management measures being employed. The measures that are in place now under the interim plan increase protections, in part, by increasing the frequency prenesting and nest surveys for state-listed and special status species and providing larger buffers for American oystercatcher chicks, as noted in the Cape Lookout Interim Protected Species Management Plan/EA. The outcome of the Cape Lookout National Seashore ORV Management Plan/EIS would also have direct long-term impacts on bird populations within the Seashore as well as within the state of North Carolina. However, whether the impact of the ORV plan would be beneficial or adverse to state-listed / special status birds would depend upon the management decisions that are made and ultimately implemented.

The replacement of the Herbert C. Bonner Bridge may have minor adverse impacts on state-listed / special status birds. Construction noise and lighting may adversely impact courting, nesting, and foraging of state-listed / special status birds. The presence of shading from the bridge and pilings driven into the substrate may also alter the optimal suitability of the beach surrounding the bridge for both nesting and foraging state-listed/special status birds in the vicinity of the impact. However, the new bridge would also

provide some benefits by allowing barrier island processes to occur more naturally than with the bridge it replaces. To the extent that the new bridge would allow the natural formation of new habitats such as overwash fans, new inlets, and low sloping beaches it might provide additional suitable habitat for state-listed / special status birds. In this case, the impact of the Herbert C. Bonner Bridge would be long-term with benefits to American oystercatchers, Wilson's plovers, and red knots in the vicinity of the bridge.

The overall combined impacts of these past, current, and future actions would be long-term minor to moderate adverse. These impacts, combined with the moderate to major long-term adverse impacts under alternative A, would result in long-term moderate to major adverse cumulative impacts.

**Conclusion.** The overall impact for each species under alternative A would be as follows:

- American oystercatcher. Impacts of resources management activities (primarily resulting from the effects surveying and field activities) would be long-term minor to moderate adverse as any surveying and lack of specific prenesting closures for this species may miss early nesters. Also, buffer distances based on bird behavior may not provide adequate protection for the species. Impacts from ORV and other recreational use would be long-term moderate to major adverse as buffers that adjust frequently based on bird behavior are more subject to non-compliance. The lack of designated VFAs, a permitting system, carrying capacity, or night-driving restrictions, and allowing pets in the vicinity of breeding birds would contribute to adverse impacts.
- Colonial waterbirds. Impacts of resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term minor to moderate adverse as surveying and lack of specific prenesting closures for colonial waterbirds may miss early nesters. Also, buffer distances (150–300 feet) may not provide adequate protection, especially if buffer distances are based on observed bird behavior and the birds are not being continuously observed/monitored. Impacts of ORV and other recreational use would be long-term moderate to major adverse as buffers may not be adequate to protect the species, and disturbance from recreational uses is more likely. The lack of designated VFAs, a permitting system, carrying capacity, or night-driving restrictions, and allowing pets in the vicinity of breeding birds would also contribute to adverse impacts.
- Wilson's plover. Impacts of resources management activities (primarily resulting from the effects of surveying and field activities) would be long-term minor adverse as the habitat for this species would be well surveyed during piping plover surveys and this species would be able to take advantage of management measures taken for piping plover as their breeding seasons and habitat requirements are similar. Also, buffer distances based on bird behavior may not provide adequate protection for the species. Some benefits may occur from incidental management of Wilson's plover during piping plover management activities, both during breeding and nonbreeding seasons. Impacts of ORV and other recreational use would be long-term moderate to major adverse as no specific management would be provided for this species, although they could utilize buffers and closures established for piping plover. The lack of designated VFAs, a permitting system, carrying capacity requirements, or night-driving restrictions, and allowing pets in the vicinity of breeding birds would also contribute to adverse impacts.
- Red knot. Impacts to nonbreeding red knots would be long-term minor adverse as their prime foraging habitat (ocean shoreline) would not be afforded protection by nonbreeding closures. Many of the surveying and field activities would occur outside of the primary time when red knot are present at the Seashore. Therefore, any impacts to this species from surveying and field activities would be long-term negligible adverse. Impacts of ORV and other recreational use would be long-term moderate adverse as no specific management would be provided for this species especially during a key life stage of wintering. The lack of designated VFAs, a permitting

system, no night-driving restrictions during the time period when red knot are present at the Seashore, and allowing ORVs, people, and pets at the Seashore during the nonbreeding season in the vicinity of this species would contribute to adverse impacts. Impacts to red knots would be lower than with other species as they would not be subject to impacts during their breeding cycle and their use of the Seashore corresponds to times of lower visitation.

Cumulative impacts under alternative A would be long-term moderate to major adverse.

### **Impairment Determination**

*Brief Description of the Condition of the Resource.* Colonial waterbirds at the Seashore include gull-billed terns, common terns, least terns, and black skimmers. While the common tern, gull-billed tern and black skimmers are not federally listed species, they have been identified as special status species due to the following designations: the gull-billed tern is listed on the USFWS 2008 Birds of Conservation Concern (USFWS 2008b) and is listed as threatened by the State of North Carolina; the common tern is listed on the USFWS 1995 list of Non-game Birds of Management Concern (USFWS 1995) and the 2008 Birds of Conservation Concern (USFWS 2008b), as well as being a North Carolina Species of Special Concern (NCWRC 2008b); and the black skimmer is listed on the USFWS 2008 Birds of Conservation Concern (USFWS 2008b), as well as being a North Carolina Species of Special Concern (NCWRC 2008b). During the period from 1977 to 2007, the number of gull-billed tern nests declined from approximately 268 to only 90, common tern nests from 2,761 to 498, and black skimmer nests from 976 to 555. Numbers of most breeding, colonially nesting shorebirds within North Carolina have declined over the past 20 to 30 years (Cohen et al. 2010; see table 29). For example, from 1977 to 2007, colonial waterbird nesting declined 30%, from 7,068 to 5,004 nests (table 29). Barrier island beaches provide important habitat for gull-billed terns, common terns, least terns, and black skimmers. Many of these beaches are severely degraded due to coastal development and associated increases in human disturbance and in predation by overabundant species. These factors have most likely contributed to the decline in colonial waterbird numbers in North Carolina, including the Seashore (Cameron and Allen 2008).

Within the Seashore, six gull-billed tern nests were recorded in 2007 on Green Island and none were found in 2008 or 2009, representing a decline from the Seashore's average of approximately 32 nests during surveys between 1977 and 2009. In 2010, one gull-billed tern nest was documented at Cape Point, but was lost before hatching. A total of 19 common tern nests were documented at the Seashore in 2008, although that number rose to 53 nests for the 2009 season. The number of least tern nests rose dramatically at the Seashore in 2009, when 577 were documented by resource management staff. Black skimmer nest numbers have sharply declined at the Seashore, with only 11 nests in 2007 and 4 nests counted in 2008. However, 61 black skimmer nests were documented in 2009 (table 30). The number of nests recorded in 2007 for three of the four species was the lowest in the history of waterbird surveys in North Carolina (Cameron and Allen 2008). With the exception of the gull-billed tern, colonial waterbird numbers at the Seashore showed substantial increases during the 2009 breeding season.

*Common terns, gull-billed terns, and black skimmers are necessary to fulfill the purposes for which the Seashore was established.* The Seashore's enabling legislation provides for the Seashore to be permanently reserved as a primitive wilderness and the unique flora and fauna and physiographic conditions prevailing in the area to be preserved. The common tern, gull-billed tern, and black skimmer, all of which have been identified as special status species, are important parts of the unique flora and fauna that the Seashore was established to preserve.

*Common terns, gull-billed terns, and black skimmers are key to the natural or cultural integrity of the Seashore or to the opportunity for enjoyment of the Seashore.* The migratory shorebirds that exist within the Seashore are part of the Seashore's significance. The common tern, gull-billed tern and black

skimmers found in the Seashore have been identified as special status species and preservation of these species are part of why the Seashore was established (preservation of the unique flora and fauna) which is key to the natural integrity of the Seashore.

*Common terns, gull-billed terns, and black skimmers are implicitly but not explicitly identified as a significant resource in the Seashore's planning documents.* The Seashore's planning documents do not provide an explicit listing of "significant resources," i.e., a list stating which resources are significant and which are not. However, the planning documents repeatedly address the flora and fauna and physiographic conditions of the Seashore, particularly migratory birds and threatened and endangered species. Common terns, gull-billed terns and black skimmers are all migratory shorebirds found at the Seashore that are an important part of the Seashore's natural resources addressed in its planning documents. Therefore it seems reasonable to conclude that the Seashore's planning documents implicitly consider the common tern, gull-billed tern, and black simmer "significant" because they are part of the fauna the Seashore is mandated to preserve.

The Seashore's 2007 Long-Range Interpretive Plan in its description of the Seashore's purpose calls out preserving and protecting the "park's natural resources" and "dynamic barrier islands that are shaped by ongoing natural processes" (Seashore's Long-Range Interpretive Plan (NPS 2007d)). The Seashore's 2006 – 2011 Strategic Plan lists preserving and protecting the "dynamic coastal barrier island system...flora and fauna that are found in a variety of habitats at the park," including "migratory birds and several threatened and endangered species" (2006 – 2011 Strategic Plan (NPS 2007b)). The Seashore's General Management Plan states: "The overall planning objective for the national seashore is to preserve the cultural resources and the flora, fauna, and natural physiographic condition, while providing for appropriate recreational use and public access to the oceanside and soundside shores in a manner that will minimize visitor use conflict, enhance visitor safety, and preserve park resources" (NPS 1984). The primary resource management objective of the Seashore as expressed in the General Management Plan, is to preserve the dynamic physiography and the characteristic ecological communities of the Outer Banks, in all units of the Seashore except for the developed areas. The Seashore's Strategic Plan states "The purpose of Cape Hatteras National Seashore is to preserve and protect significant segments of barrier island coastline for the benefit and enjoyment of the people and to provide for recreational visitor use consistent with that purpose." The Seashore's Strategic Plan describes the significance of the Seashore as follows:

This dynamic coastal barrier island system continually changes in response to natural forces of wind and wave. The flora and fauna that are found in a variety of habitats at the park include migratory birds and several threatened and endangered species.

In addition to these broader planning documents that provide management for the flora and fauna, migratory birds and threatened and endangered species as part of the resources of the Seashore, the Seashore's Interim Protected Species Management Strategy provides management measures specifically for colonial waterbirds including common tern, gull-billed tern, and black skimmer.

*Analysis.* Implementation of alternative A has the potential for impairment to common terns, gull-billed terns, and black skimmers because it may result in a decrease in Seashore population levels or a failure to restore levels that are needed to maintain a sustainable population in the Seashore. Numbers of these three species nesting in the Seashore have already declined substantially and are at sufficiently low levels for colonial nesting species that, over the long term life of the plan, measures such as prenesting closures and larger buffers for these species, which are not provided by alternative A, would likely be needed to restore Seashore population levels to the point that it could be determined that impairment would not result. Alternative A would designate the ocean and inlet shoreline and existing soundside routes as designated ORV routes and permit year-round unrestricted night driving on the beach. Under alternative A,

prenesting closures would not be installed for common tern, least tern, gull-billed tern, and black skimmer that nest in the Seashore. For colonial waterbirds that nest at the spits, Cape Point, and South Beach, the piping plover prenesting closures would provide protection from disturbance, if they nest inside the closures. However, other nesting locations used by these species in recent years would not be protected with prenesting closures. For colonial waterbirds, if territorial behavior / courtship behavior is observed during two consecutive surveys, then observation would increase to three times a week and a buffer would be established. If scrapes or eggs are observed, observation would increase to three times a week and a buffer established. For colonial waterbird nests, a 150- to 300-foot buffer would be established, with the exact distance within that range dependent on best professional judgment based on adult reaction to human disturbance. The smaller buffers in the 150- to 300-foot range would likely be inadequate for the common tern, gull-billed tern, and black skimmer, which are more sensitive to disturbance than least terns. Alternative A does not require that the larger 300-foot buffers be provided for these species. Even if provided, they are smaller than recommended in some of the scientific literature for these species, which are more easily disturbed than least terns. Colonial waterbirds with unfledged chicks would be observed at one-day to two-day intervals. Observation would be more frequent when broods are mobile. Colonial waterbird unfledged chick buffers would initially be 150- to 300-feet and then vary in size within that range based on best professional judgment and adult reaction to human disturbance. Although, under alternative A the need to adjust buffers frequently would result in disturbance, the buffers would help prevent, but not eliminate, further disturbance. If installation of buffers or adjustments to the buffer are not made quickly or if nests are missed by observers, the birds may be adversely affected. Because chick buffers are relatively small, would be variable based on adult response to human disturbance and on chick behavior (when chicks are mobile), and could change frequently, additional disturbance to these species may occur, including from the increased chances for intentional or unintentional visitor noncompliance with the closures. Alternative A would provide a 24-hour-per-day ORV corridor along the ocean and inlet shoreline and existing soundside routes of the Seashore including, where beach width is sufficient, a corridor adjacent to areas used by these species. This would increase opportunities for noncompliance with resource protection closures. Although most visitors respect closures, closure intrusions by vehicles, pedestrians, and pets may result in harassment, injury, or mortality to one or more individuals. Under alternative A, ORVs would bring more people into the vicinity of breeding areas used by these three species, where trash associated with recreation use would continue to attract mammalian and avian predators. Predation is known to adversely affect the reproductive success of shorebirds at the Seashore. The indirect impacts of attracting predators would be detectable and beyond the level of harm that can occur naturally, but are not expected to result in large declines in population because the Seashore takes management action to protect state-listed species from predation.

Nonbreeding closures would not be established for these species, although they could use the interior habitat at spits and at Cape Point that would be closed to ORV and other recreational use for piping plover during the nonbreeding season, resulting in year-round protected interior habitat in these areas for all species. No areas of shoreline would be protected for nonbreeding shorebird foraging under alternative A. Effects from commercial fishing would not be observable or measurable and would be well within natural fluctuations because the special use permit under which commercial fishing is managed prohibits entering resource closures and because a relatively small number of commercial fishermen operate inside the Seashore. Under alternative A, pets are allowed on the beach year-round at the Seashore, but prohibited from the landward side of the posts delineating the ORV corridor at the spits and Cape Point and inside bird closures. Because some visitors do not keep their pets restrained on a 6-foot or shorter leash or crated as required, allowing pets in the vicinity of resource closures could result in harassment, injury, or mortality to one or more individuals.

The plan/EIS analysis evaluated impacts on these species from ORV and other recreational use and from lack of specific management measures, such as (1) prenesting closures, (2) winter foraging closures on the shoreline, (3) buffer distances that may not provide adequate protection (especially if buffer distances

are based on observed bird behavior and the birds are not being continuously observed), (4) buffer distances that even at the large end of the allowed range may not be adequate for the more sensitive species of colonial waterbirds, (5) and lack of designated non-ORV areas. Overall, the impacts to gull-billed tern, common tern, and black skimmer were deemed by the plan/EIS impact analysis to be moderate to major adverse because implementation of alternative A could result in substantial declines in population numbers or failure to restore sufficient numbers to maintain a sustainable population in the Seashore for these three species.

For several reasons, the colonial waterbird data for the Seashore are not sufficient to support a trend analysis for the two years (2006 and 2007) that management under alternative A was in effect. A nest survey was not conducted in 2006; annual nest surveys did not begin until 2007; and survey methodology varied over the years, including among the recent annual surveys. For example, the Seashore's 2008 annual report for colonial waterbirds notes that an important factor to recognize when comparing the 2008 breeding season to the previous season is that more emphasis was placed on collecting colonial waterbird data in 2008. Due to staffing levels in 2008, it was possible to spend more time monitoring the waterbird colonies. Colonies were surveyed on foot at least once a week by small groups of bio-technicians, producing relatively reliable nest and chick counts. In previous years (including 2007), colonies were rarely walked through and were usually surveyed by one bio-technician telescoping the colony of birds. Because of the differences in survey techniques, it is difficult to accurately compare 2008 data with 2007 data. Additionally, one overview of the status of gull-billed terns commented on the lack of population data for the species and noted that counts from single colonies or even single regions may be impossible to interpret in isolation

(<http://www.natureserve.org/explorer/servlet/NatureServe?searchName=Gelochelidon+nilotica>). In the 2007 survey, which occurred under the Interim Strategy, 6 gull-billed tern nests, 109 common tern nests, and 11 black skimmer nests were documented at the Seashore. In 2008, 4 black skimmer nests and 19 common tern nests were recorded at the Seashore under procedures modified by the consent decree. In 2009, 61 black skimmer and 53 common tern nests were found.

The analysis in the plan/EIS of cumulative impacts combined the effects of alternative A with effects of other past, present, and future planned actions in and around the Seashore, such as major dredging and maintenance dredging of Oregon Inlet, storms and other weather events, local development, predator management by the Seashore, commercial fish harvesting, and increased interpretative programs as part of the Seashore's long-range interpretive plan. The plan/EIS impact analysis deemed the cumulative impacts to be moderate to major adverse for the black skimmer, common tern, and gull-billed tern because a decrease in Seashore populations levels or a failure to restore levels that are needed to maintain a sustainable population in the Seashore could result. Therefore the black skimmer, common tern, and gull-billed tern impacts have the potential to result in impairment.

## **Impacts of Alternative B: No Action—Continuation of Management under Terms of the Consent Decree**

### **Resources Management Activities**

*Establishment of Prenesting Closures.* As with alternative A, under alternative B specific prenesting closures would not be established for American oystercatchers, colonial waterbirds, or Wilson's plover. For American oystercatchers and colonial waterbirds, closures would be established only when a territory is established or a nest is located. Although these species would be able to utilize prenesting closures for piping plovers that are in effect by March 15, no specific prenesting closures for these other species would be established at other locations, including many areas that had been used for nesting in the past three years. The piping plover prenesting closures would be established at Bodie Island Spit, Cape Point, South Beach, Hatteras Inlet Spit, North Ocracoke Spit, and South Point by March 15 and would be

delineated to incorporate to the maximum extent the areas delineated in the 2008 prenesting closure maps and would include to the maximum extent possible the soundside intertidal zone, areas of moist soil habitat, ocean backshore, dunes, dry sand flats, overwashes, blowouts, and areas of the ocean tidal zone consistent with the 2008 prenesting closures. These closures would remain in place until the later part of July 15 or two weeks after the last chick within the area has fledged, as determined by two consecutive monitoring events.

As under alternative A, during prenesting, a 33-meter (108-foot) wide ORV and pedestrian corridor would be established and pedestrian access would be prohibited outside of ORV corridors including breeding areas beyond the symbolic fencing. The ORV/pedestrian corridor would be delineated with posts placed up to 33 meters (108 feet) above the high tide line. In areas of reduced corridor width (i.e., narrower than 33 meters [108 feet]), a speed limit of 10 mph would be posted. All prenesting closures would be removed when areas have been abandoned for a two-week period. In addition, under alternative B in all locations not in front of the villages, outside of the piping plover prenesting areas and open to ORV use, the NPS would provide an ORV-free zone from March 15 to November 30 in the ocean backshore at least 10 meters (32 feet) wide and running the length of the site, wherever backshore habitat exists, provided there is sufficient beach width to allow an ORV corridor of at least 20 meters (66 feet) above the mean high tide line. This ORV-free zone would be adjacent to the toe of the primary dune whenever a primary dune exists.

Under alternative B, the implementation of prenesting closures for piping plover at the inlets, Cape Point, and South Beach and the ocean backshore closures at other locations by March 15 would be early enough in the breeding season that it would be beneficial to early nesting American oystercatchers, as well as to other species that typically nest later. Because there are no specific prenesting closures for state-listed and special status species, apart from the piping plover prenesting areas, many areas that had been used for nesting in the past three years would not be protected until breeding activity is observed. There would be overall long-term moderate adverse impacts to these species, except for minor adverse impacts for Wilson's plover, which generally would nest within the prenesting areas established for piping plover.

*Surveying and Monitoring.* Surveying and monitoring for state-listed and special status species would occur as described for alternative A. In addition, under alternative B trained NPS biologists or field technicians would survey Cape Point and South Beach, Hatteras Inlet Spit, and the northern and southern ends of Ocracoke at least once every two days from March 15 to April 15, and daily from April 16 to July 15. Seashore staff would monitor Bodie Island Spit at least daily from March 15 to July 15.

Surveying would likely have long-term minor adverse impacts, but overall surveying would provide long-term benefits to the species. Under alternative B, impacts from species surveying measures would have more of a beneficial effect on nesting state-listed/special status species and their habitat than alternative A due to earlier and increased monitoring of the inlets, Cape Point, and South Beach. Alternative B would also have a more beneficial effect on state-listed and special status species due to piping plover prenesting areas being installed by March 15, instead of April 1 as under alternative A. This would likely reduce disturbance of other species present at these locations during the early part of the breeding season.

Although surveying would provide substantial benefits to the species from data collected, surveying would bring people and/or essential vehicles into direct short-term contact with state-listed/special status species and their habitat, as described under alternative A. Therefore, under alternative B, species surveying could likely have long-term minor adverse impacts from the introduction of human disturbance during these activities, but overall surveying would provide long-term benefits to the species as it would allow the Seashore to better manage the species. Many of the surveying and field activities would occur outside of the primary time when red knot are present at the Seashore. Therefore, any impacts to this species from surveying and field activities would be long-term negligible adverse.

*Buffer/Closure Establishment.* If breeding behavior, including but not limited to territorial behavior, courtship, mating, confirmed scrapes, or other nest-building activities, is observed outside of existing closures, Seashore staff would automatically establish prescribed species-specific buffers, rather than providing flexible buffers based on observations of bird behavior as would occur under alternative A. If the NPS observes breeding behavior (as defined in the consent decree) of American oystercatchers, colonial waterbirds, or Wilson's plover, the NPS would establish the prescribed buffers as quickly as possible, but always within eight daylight hours. Upon discovery of an active nest or chicks that are outside an existing closure, protective measures would be taken immediately to close and establish the buffers described above. Symbolic fencing with the applicable buffer distances stated above would be installed as soon as NPS staff can reasonably be mobilized to install the fencing, but always within six daylight hours.

The size and timing of these buffers would have a beneficial effect for American oystercatchers, colonial waterbirds, and Wilson's plover. The NPS would rely upon monitoring to detect the presence of breeding activity in many locations that are otherwise open to ORV use and associated recreational activities. Under alternative B, people, their pets, and vehicles could still come into direct contact with state-listed/special status species prior to the detection of breeding activity by NPS staff, although it would be to a much lesser extent than alternative A. Larger buffer distances and timely installation of resource closures for observed breeding behaviors would minimize disturbance to pairs during territory establishment. These activities, as with surveying, are known risk factors. As described under alternative A, American oystercatchers at the Seashore can begin courting and nesting as early as mid-February or early March and be particularly sensitive to disturbance at that time (Cohen et al. 2010). Hence, a March 15 start to management could mean that early nesting American oystercatchers, especially those that establish territories outside of recently used nesting areas, would not be fully protected under alternative B.

Under alternative B, buffers/closures would be established for breeding behavior and nesting American oystercatchers for a distance of 150 meters (492 feet). A buffer of 200 meters (656 feet) would be established for unfledged oystercatcher chicks. For the least tern, a colonial waterbird, a buffer/closure of 100 meters (328 feet) would be established for breeding behavior and nesting and a buffer of 200 meters (656 feet) would be established for unfledged least tern chicks. For all other colonial waterbirds, a buffer/closure of 200 meters (656 feet) would be established around the nest or colony based on observed bird behavior for breeding, nesting, and protection of unfledged chicks. When multiple species are present, the greatest applicable buffer distance would be used. If NPS staff observe disturbance from ORVs and/or pedestrians, buffers would be expanded in 50-meter (164-foot) increments until no disturbance occurs. If a deliberate violation occurs that disturbs wildlife or vandalizes nests or fencing, the buffer would be expanded by 50 meters (164 feet) on the first offense. If there are multiple occurrences in the same area, the buffer would be expanded by 100 meters (656 feet) and 500 meters (1640 feet) for the second and third violations respectively. If a violator is apprehended, the NPS would not be required to institute expanded buffers.

In contrast to alternative A, when resource closures using the prescribed buffers are created around nests under alternative B, the ORV corridor would not be reduced to accommodate an ORV corridor. When resource closures are created or expanded around observed breeding activity or nests, due to the larger buffer distances provided under alternative B, the ORV corridor would likely be closed in most cases and a bypass in the immediate vicinity of the site would be precluded. Unfledged chick buffers would follow a prescribed distance, and the size of the buffer would be maintained as chicks move. Although it is possible under alternative B, as described under alternative A, that observations of chick movements may not be sufficient to adjust buffers such that they always ensure timely protection of chicks from ORV/pedestrian impact, the increased monitoring and larger buffer/closure areas under alternative B would likely reduce any potential effects to negligible. As under alternative A, an alternate

ORV/pedestrian access route would be provided to open areas beyond the closure, if possible. The ORV corridor would be reopened in recent or current nesting areas after chicks fledge. As under alternative A, no additional buffers or closures would be provided to foraging adult state-listed/special status species under alternative B.

Under alternative B, establishment of increased buffer zones around breeding/nesting/fledging areas for all nesting state-listed/special status species, implementation of stipulations for increasing buffer zones should there be a violation of these zones from ORV or pedestrian use, and posting of nests with symbolic fencing would provide some deterrent to the entry of people, pets, and ORVs into their habitats and greatly reduce the possibility of disturbance to species, including first time breeders, and habitat compared to alternative A.

By clearly defining triggers for closure establishment, increasing closures sizes and reducing the time it takes to implement closures to protect species, alternative B would provide more benefits to American oystercatchers and colonial waterbirds by reducing disturbance to potential and nesting pairs. If breeding behavior, including but not limited to territorial behavior, courtship, mating, confirmed scrapes, or other nest-building activities, is observed outside of existing closures, the NPS would automatically establish prescribed species-specific buffers, rather than providing flexible buffers based on observations of bird behavior as would occur under alternative A. If breeding behavior is observed, appropriate buffers would be established within eight daylight hours. If an active nest or chicks are discovered outside of an existing closure, protective measures would be established immediately and appropriate buffers would be established within six daylight hours. Symbolic fencing consisting of wooden post, bird usage signs, string, and flagging tape would be installed as soon as NPS staff can be reasonably mobilized to install the fencing.

With larger buffers and more timely closures for breeding/nesting/fledging areas under alternative B, impacts from closures/buffers under alternative B would be long-term minor adverse.

*Wintering/Nonbreeding Management.* Nonbreeding surveys for American oystercatchers, Wilson's plover, and red knots would be conducted according to the NPS SECN survey protocol, with no nonbreeding surveys for colonial waterbirds. These surveying activities would have minor impacts (due to human disturbance as discussed above) and long-term benefits related to the increase in knowledge about the species. Lack of nonbreeding surveys for colonial waterbirds would have long-term moderate adverse impacts, as data would not be collected to assist in the determination of future management (nonbreeding) of these birds.

No nonbreeding closures would be established for state-listed/special status species, although these species could utilize the nonbreeding closures for piping plover that would include suitable interior habitats at spits and at Cape Point year-round. Being able to utilize other species closures would have some long-term benefits, as some protection is offered during this sensitive life stage. However, these closures would not be specific to the state-listed/special status species and would not include ocean beach habitat, resulting in some long-term minor adverse impacts. Wilson's plover would benefit from nonbreeding closures for piping plover as they utilize similar nonbreeding habitat.

*Education and Outreach.* Under alternative B and as described under alternative A, the public would continue to receive information at the visitor centers and ORV access points about state-listed/special status species and their ecology and the measures the Seashore is taking to protect the species. The public would also be informed through weekly Beach Access Reports, weekly Resource Management Reports, Google Earth, and information available on the Seashore's website. As with alternative A, public outreach as part of species management would have long-term beneficial impacts, with the expanded outreach having greater impacts than alternative A.

*Overall Impact of Resources Management Activities.* The overall impact of resources management activities (primarily resulting from the effects of surveying and field activities) for each species under alternative B would be as follows:

- American oystercatcher. Establishment of piping plover prenesting closures earlier in the season that could be used by oystercatchers and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts related to human disturbance during field activities, resources management activities on the whole would provide information and result in actions that would be beneficial to the species.
- Colonial waterbirds. Establishment of piping plover prenesting closures earlier in the season that would be used by some colonial waterbird species and establishment of larger, pre-set buffers would result in long-term beneficial impacts to colonial waterbirds. While there would still be minor adverse impacts related to human disturbance during field activities, resources management activities on the whole would provide information and result in actions that would be beneficial to the species.
- Wilson's plover. Establishment of piping plover prenesting closures earlier in the season that could be used by other species and establishment of larger, pre-set buffers for piping plover, used by Wilson's plover, would result in long-term beneficial impacts to Wilson's plover. While there would still be minor adverse impacts related to human disturbance during field activities, species surveying and field activities on the whole would provide information and result in actions that would be beneficial to the species.
- Red knot. Many of the surveying and field activities would occur outside of the primary time when red knot are present at the Seashore. Therefore, any impacts to this species from surveying and field activities would be long-term negligible adverse. The red knot would benefit from extended breeding season closures for other species and from wintering closures for piping plover at the inlets and Cape Point, although benefits would be minimal as red knot prefer ocean beach habitat. Impacts to nonbreeding red knot would be long-term minor adverse as their prime foraging habitat (ocean shoreline) would not be afforded protection by nonbreeding closures.

## **ORV and Other Recreational Use**

*ORV and Pedestrian Access.* Under this alternative, visitors would be allowed to operate ORVs on all the ocean and inlet shoreline and on the existing soundside routes, 24 hours per day year-round, subject to temporary resource closures, seasonal ORV closures in front of the villages, and temporary ORV safety closures (see figure 2, chapter 2, alternative A and B maps).. There would be no designated VFAs, although temporary closures would occur for resource protection and safety reasons, and seasonal closures would occur in front of the villages. Alternative B would provide for closures of piping plover prenesting areas, which may benefit other species, as well as closures based on observations of breeding behavior, foraging, and chick movements. Under the consent decree, for the benefit of all bird species, from March 15 to November 30, in all locations not in front of villages, outside of the prenesting areas, and open to ORV use, the NPS would provide an ORV-free zone in the ocean backshore at least 10 meters wide and running the length of the site, wherever backshore habitat exists, provided there is sufficient beach width to allow an ORV corridor at least 20 meters above the mean high tide line. This zone shall be adjacent to the toe of the primary dune whenever a primary dune exists (i.e., ORVs should be restricted to a corridor between the mean high tide line and the edge of the zone of the protected backshore).

Under alternative B and as described in the previous section, staff would monitor shorebird breeding habitat for signs of breeding behavior and human disturbance and to ensure the timely installation of resource closures and the adequacy of prescribed buffers. Resource protection areas would not be adjusted to accommodate ORV use. Based on the size of the prescribed buffers, the ORV corridor is likely to be closed at any location in which breeding activity is observed.

Recreation and commercial fishing use under the restrictions defined in alternative B would greatly reduce the proximity of ORVs, essential vehicles (for safety, enforcement, etc.), pedestrian, pets, and other recreation activities to state-listed/special status species and their habitat compared to alternative A. It is likely that outside of existing resource protection closures, some species could still be disturbed, albeit briefly, until NPS monitoring detects the breeding activity and establishes the prescribed buffers. Even after closures have been established, American oystercatchers could leave the closures to forage and during this time would not be protected from disturbance. Compliance with closures may not be absolute, resulting in minor to possibly moderate adverse impacts if non-compliance occurs. Disturbance during the most critical periods of reproduction and within key habitats could occur, resulting in direct mortality, abandonment or loss of habitat, if closure compliance is lacking and/or if the breach of the closure occurs in the earlier life stages, even with the measures to increase buffers when a violation of the closure occurs.

Under alternative B, as described under alternative A, there would be no year-round or seasonal closures specifically to protect key red knot habitat. Recreation and commercial fishing activities that occur in the months when red knots are in residence on beaches in the Seashore have the potential to impact resting and foraging red knots from vehicle use and associated noise and presence of people and pets. Of particular concern is when these disturbance factors result in red knots being forced to fly while they are foraging. Frequent escape flights means that time spent foraging is reduced and replaced by an increase in time spent flying, resulting in the chance that birds would not be able to add the body fat they need for their long-distance migration. Impacts to red knots would be long-term minor to moderate adverse.

As noted in chapter 3, a 3-year study on Cape Cod and Fire Island, New York (Kluft and Ginsberg 2009), found that higher ORV traffic resulted in dispersal and desiccation of the wrack line, thereby reducing the population of invertebrates in that area. Alternative B would allow for beach driving in the wrack during the day outside of resource closures, but would maintain nighttime closures. Resource closures that are in effect 24 hours per day and nighttime closures would reduce disturbance in this area for a portion of the year. Overall impacts to invertebrates would be long-term and minor (as discussed later in this chapter), and would reduce the food source available to the state-listed and special status species at the Seashore that rely on this food source, but to a lesser degree than if night driving was permitted, resulting in long-term minor impacts.

*Night-Driving Restrictions.* Under alternative B, all recreational ORV traffic would be prohibited in the ocean intertidal zone, ocean backshore, and dunes, from 10:00 p.m. until 6:00 a.m. between May 1 and September 15. However, from September 16 to November 15, night-driving permits would be available for authorized nonessential driving between the hours of 10:00 p.m. and 6:00 a.m. The permit would contain restrictions on light use during the September 16 to November 15 permitted night-driving period. Furthermore, the NPS retains the discretion to limit night driving to certain areas or routes, based on resource protection considerations. American oystercatchers, Wilson's plover, and red knot are known to be active at night (Simons and Schulte 2008; Morrier and McNeil 1991; Niles et al. 2007) and would be subject to disturbance from vehicular and pedestrian disturbance. This disturbance can impact their foraging behavior and has been shown to result in disorientation and even abandonment of American oystercatcher chicks (Simons and Schulte 2008). Restrictions on night driving under alternative B would provide long-term benefits to state-listed/special status species; however, night driving could still result in long-term minor adverse impacts during the time when night driving is allowed by permit. Further, night-

driving restrictions that begin after dark, in this case 10:00 p.m., do not offer full nighttime protection to the species.

*Commercial Fishing.* Commercial fishing restrictions under alternative B would be similar to those under alternative A, with those holding commercial fishing permits restricted from night driving from 10:00 p.m. until 5:00 a.m. (as opposed to 6:00 a.m. for recreational users) from May 1 to September 15. As with recreational users, commercial fishing permit holders can get a permit for night driving from September 16 to November 15. Presence of commercial fishing operations would have a long-term negligible adverse impact, with beneficial impacts from night-driving restrictions.

*Permit/Carrying Capacity Requirements.* As described above, alternative B would require a fall seasonal night-driving permit, although the educational information provided by the permit would not be relevant to bird species, which would limit the beneficial impacts of this requirement. Given the lack of prenesting closures for these species outside of the piping plover prenesting closures, with more immediate, larger buffers and longer lasting closures once breeding behavior is observed, the lack of a carrying capacity would have long-term minor adverse impacts to most state-listed/special status species that nest on Seashore beaches, as unrestricted numbers of ORVs would be allowed in recent breeding areas prior to the implementation of resource closures increasing the potential for disturbance. For American oystercatchers that regularly forage on the ocean shoreline and on the soundside outside of resource closures, there would be the potential for long-term minor to moderate adverse impacts as they forage in areas used by ORVs, as described under alternative A.

*Pet/Other Recreational Activity Restrictions.* Alternative B would have the same restrictions on camping, beach fires, and pets as under alternative A, with the addition of no ORV use from 10:00 p.m. to 6:00 a.m. during May 1 to September 15, resulting in benefits to state-listed/special status species. As with alternative A, there is the potential for non-compliance with pet regulations that would be mitigated by the prohibition of pets from the landward side of the posts delineating the ORV corridor at the spits and Cape Point, the prohibition of pets within symbolic fencing around any bird closure area, and through education and outreach efforts via the Seashore field personnel and partnerships with local volunteers and organizations, and would result in long-term minor adverse impacts, due to non-compliance.

*Overall Impact of ORV and Other Recreational Use.* The overall impact of ORV and other recreational use for each species under alternative B would be as follows:

- American oystercatcher. Establishment of prenesting closures for piping plover earlier in the season, implementation of larger, more immediate buffers, longer lasting closures for American oystercatchers once breeding behavior occurs, and night-driving restrictions would benefit the American oystercatcher. However, recreational use, with no carrying capacity, would still occur in the vicinity of this species and the established buffers may not be large enough to afford adequate protection. Because the birds would not be under constant observation, disturbance may go undetected and implementation of adequate buffers may be delayed in some nesting locations. Compliance with closures may not be absolute, resulting in minor to moderate adverse impacts if non-compliance occurs. Further adverse impacts would result from allowing pets in the Seashore during breeding season, resulting in the possibility of non-compliance with these regulations. Because of these factors, impacts to American oystercatchers from ORV use and other recreational activities would be long-term moderate adverse.
- Colonial waterbirds. Impacts to colonial waterbirds from ORV and other recreational use would be long-term moderate adverse, for the same reasons as American oystercatchers under this alternative.

- Wilson's plover. Impacts to Wilson's plover from ORV and other recreational use would be long-term minor to moderate adverse. Although this species would face the same adverse impacts as American oystercatchers and colonial waterbirds, it also tends to utilize closures for piping plover and would therefore be provided slightly more protection than other state-listed/special status species.
- Red knot. Impacts to red knots from ORV and other recreational use would be long-term moderate adverse as no specific management would be provided for this species especially during a key life stage of wintering. Although this species may benefit from longer lasting breeding season closures for other species and from winter closures established for piping plovers, the lack of designated VFAs, a year-round permitting system, no night-driving restrictions when red knots are at the Seashore, and allowing pets at the Seashore during the migrating/nonbreeding season would contribute to these adverse impacts.

**Cumulative Impacts.** Cumulative actions and their associated impacts under alternative B would be the same as those described under alternative A. Although alternative B does provide greater protection that would be beneficial to state-listed / special status bird species, the adverse effects on birds from other actions occurring in the region would still exist. The overall combined impacts of these past, current, and future actions would be long-term minor to moderate adverse. These impacts, combined with the long-term moderate adverse impacts under alternative B, would result in long-term moderate adverse cumulative impacts.

**Conclusion.** The overall impact to each state-listed and special status species under alternative B would be:

- American oystercatcher. While there would still be minor adverse impacts related to human disturbance during species surveying and field activities, on the whole these activities would provide information and result in actions that would be beneficial to the species. Establishment of prenesting closures for piping plover earlier in the season, implementation of larger more immediate buffers and longer lasting closures for American oystercatchers once breeding behavior occurs, and night-driving restrictions would result in long-term benefits for this species. Recreational use, with the lack of designated VFAs, year-round permits, or carrying capacity requirements, would still occur in the vicinity of this species. Because the birds would not be under constant observation, disturbance may go undetected and implementation of adequate buffers may be delayed in some nesting locations. Compliance with closures may not be absolute, resulting in minor to possibly moderate adverse impacts if non-compliance occurs. Further adverse impacts would result from allowing pets in the Seashore during breeding season, resulting in the possibility of non-compliance with these regulations. Because of these factors, impacts to American oystercatchers from recreation and other activities would be long-term moderate adverse.
- Colonial waterbirds. Impacts and benefits of surveying and field activities, and impacts of recreation and other activities, would be the same as described for American oystercatchers above for the same reasons. Because of these factors, impacts to colonial waterbirds could be long-term moderate adverse.
- Wilson's plover. Although this species would face the same adverse impacts as American oystercatchers and colonial waterbirds, it also tends to utilize closures for piping plover and would therefore be provided slightly more protection than other state-listed/special status species. Impacts to Wilson's plover from recreation and other activities would be long-term minor to moderate adverse.

- **Red knot.** Many of the surveying and field activities would occur outside of the primary time when red knot are present at the Seashore. Therefore, any impacts to this species from surveying and field activities would be long-term negligible adverse. The red knot would benefit from extended breeding season closures for other species and from wintering closures for piping plover at the inlets and Cape Point, although benefits would be minimal as red knot prefer ocean beach habitat. Impacts to nonbreeding red knot would be long-term minor adverse as their prime foraging habitat (ocean shoreline) would not be afforded protection by nonbreeding closures. Impacts of ORV and other recreational use would be long-term moderate adverse as no specific management would be provided for this species especially during a key life stage of wintering, increasing the possibility of disturbance to the species from recreational use. The lack of designated VFAs, allowing night driving during the time period when red knot are present at the Seashore, and allowing ORVs, people, and pets at the Seashore during the nonbreeding season in the vicinity of this species would contribute to adverse impacts.

Cumulative impacts under alternative B would be long-term minor to moderate adverse.

## **Impacts of Alternative C: Seasonal Management**

### **Resources Management Activities**

*Establishment of Prenesting Closures.* Under alternative C, the NPS would establish SMAs based on an annual habitat assessment for management of all breeding shorebirds and subject to periodic review. Each SMA would be under ML1 or ML2 management procedures, as described in table 10 (chapter 2). All breeding shorebird SMAs would be posted as prenesting closures using symbolic fencing by March 15 at sites involving American oystercatchers and Wilson's plover and by April 15 at sites involving colonial waterbirds. If multiple species exist on each site, closures would begin on the earliest date. Proactive closures of these areas would provide long-term beneficial impacts to state-listed/special status species, greater than those under alternatives A and B, which do not offer this wide a range of protection.

*Surveying and Monitoring.* Surveys of prenesting closures for all state-listed/special status species would occur three times per week. Surveys for American oystercatchers and Wilson's plover would begin on March 15 and surveys for colonial waterbirds would begin on May 1. Surveys for suitable habitat outside of SMAs would also occur three times per week once breeding pairs are present.

The NPS would conduct nest surveys from a distance for American oystercatchers and Wilson's plover at least three times per week in areas managed under ML1 procedures. Colonial waterbirds in areas with ML1 procedures would be observed at least three times per week from a distance that does not disturb the birds. Nest count estimates would be conducted during the peak nesting period for each species, which generally is during the last week of May and the first week of June, but could be later, especially for black skimmers. For all species that have incubating birds that cannot be observed from a distance, continuation of incubation and/or status of the colony would be determined on a weekly basis (or as staff is available). The NPS would observe nests under ML2 procedures daily from a distance as long as this can be performed without disturbing the colony or incubating bird. For incubating birds that cannot be observed from a distance, nests/colonies would be checked every three days with minimum disturbance to the incubating bird and/or colony. Colonial waterbird colonies would be surveyed for hatching (approximately 21 days after initial nest observations).

For unfledged chicks, the NPS would survey broods and colonies every other day under ML1 procedures. Under ML2 procedures, American oystercatcher, Wilson's plover, and colonial waterbird chicks would be observed once daily. For American oystercatchers and Wilson's plover, observation ends once chicks have fledged. For colonial waterbirds, a survey would be conducted during peak fledge (approximately 20

days after hatch counts). Observations would end after no unfledged chicks have been observed on three consecutive surveys.

Under alternative C, surveys would concentrate in established SMAs, which may not detect American oystercatchers or colonial waterbirds that establish territories in new habitat. However, surveying under alternative C would increase knowledge on how and when special status/state-listed species use the Seashore and enable adaptive management initiatives, which would contribute to better management.

Pre-nesting surveys under alternative C would not be as frequent as those under alternatives A and B; however, due to the designation of SMAs and suitable habitat surveys outside of SMAs, effects of survey times to implement closures would be the same. Under alternative C, under ML1 procedures less monitoring of nests would occur; however there would be no ORV or pedestrian access allowed. Under ML2 procedures, birds would be monitored more frequently (the same as nesting areas under alternatives A and B) due to the presence of an ORV and/or pedestrian corridor. Alternative C would likely have long-term minor adverse impact on nesting state-listed/special status species from survey time and frequencies during the pre-nesting and nesting season at the Seashore, with overall long-term beneficial impacts from the species protection measures that result from surveying activities. Many of the surveying and field activities would occur outside of the primary time when red knot are present at the Seashore. Therefore, any impacts to this species from surveying and field activities would be long-term negligible adverse.

*Establishment of Buffers/Closures.* Under alternative C, as described under alternative B, closure of pre-nesting areas by March 15 (in most cases) and/or April 15 for colonial waterbirds would have a more beneficial effect due to closures occurring earlier, ensuring a reduction of disturbance for colonial waterbirds during breeding (courtship, mating, scrapes, etc.). As described above, under alternative C SMAs would be established and managed under ML1 or ML2 procedures. ML1 procedures would not allow ORV or pedestrian access when pre-nesting closures are in effect. ML2 procedures (Bodie Island Spit, Cape Point, and South Point) would establish a narrow pedestrian access corridor. Upon first observation of breeding activity, the standard buffers would apply, which depending on the circumstances may close the access corridor. Pets, kite flying, ball and Frisbee tossing, or similar activities would be prohibited in access corridors while pre-nesting closures are in effect. If no breeding activity is observed in SMAs by July 31, or two weeks after all chicks have fledged (whichever is later), pre-nesting closures would be adjusted to the configurations of Nonbreeding Shorebird SMAs (established from annual monitoring of presence, abundance, and behavior of migrating and wintering shorebirds from July through May).

Under alternative C, a total of seven SMAs would be closed to ORV and pedestrian access and managed under ML1 procedures from March 15 through October 14 due to multiple species closures. A total of three SMAs would be managed under ML2 procedures and would be closed to ORV use from March 15 through October 14, but would provide a pedestrian access corridor generally below the high tide line and no greater than 10 meters (30 feet) above the high tide line. Buffers would be applied to courtship/mating, nesting, and unfledged chick activities both within and outside of designated SMAs. All SMAs would maintain a 300-meter (900-foot) buffer during all activities for all state-listed / special status bird species. ML2 buffer areas would vary by species and activity. ML2 procedures for American oystercatchers would establish 150-meter (450-foot) buffers for breeding and nesting activities and 200 meters (600 feet) for unfledged chick activity. Under ML2 procedures, buffers for least terns, a colonial waterbird, would be 100 meters (300 feet) for breeding and nesting activities and 200 meters (600 feet) for unfledged chick activity. All other colonial waterbird buffers under ML2 procedures would be 200 meters (600 feet) for breeding, nesting, and unfledged chick activities. For areas where breeding activity is observed outside of pre-nesting areas, ML1 procedures would determine the buffers. For alternative C, buffers would be removed outside of pre-nesting areas if no breeding activity is observed for a two-week period or when

associated breeding activity has concluded, whichever is later. If breeding activity or scraping is observed outside of an existing closure, buffers would be expanded to accommodate the designated buffer for the particular management level (ML1 or ML2). Under alternative C, as described under alternative B, if NPS staff observe disturbance from ORVs and/or pedestrians, buffers would be expanded in 50-meter (164-foot) increments until no disturbance occurs. Under alternative C, for all species buffers/closures, vehicles and/or pedestrians may be allowed to pass through portions of the buffer or closures that are considered inaccessible to chicks because of steep topography, dense vegetation, or other naturally occurring obstacles. Establishment of SMAs and implementation of larger buffer sizes would have long-term beneficial impacts to state-listed and special status species.

Under alternative C, as described under alternatives A and B, observations of chick movements may not be sufficient to adjust buffers such that they ensure protecting chicks from ORV/pedestrian impact; however, increased larger buffer/closure areas under alternative C would likely reduce any potential effects to negligible. As described under alternatives A and B, no additional buffers or closures would be provided to foraging adult state-listed/special status species under alternative C, although species would likely indirectly benefit from the protections provided to piping plover foraging habitat.

Under alternative C, establishment of SMAs with ML1 and ML2 procedures, increased buffer zones around breeding/nesting/fledging areas for all nesting state-listed/special status species, and posting of nests with symbolic fencing would not only eliminate ORV and pedestrian use in multiple high use bird areas, but also provide a major deterrent to the entry of people, pets, and ORVs into habitats and greatly reduce the possibility of disturbance to species, including first time breeders, and habitat compared to alternatives A and B.

Under alternative C, as described under alternatives A and B, oystercatchers at the Seashore can begin courting and nesting as early as mid-February or early March and be particularly sensitive to disturbance at that time (Cohen et al. 2010). Hence, a March 15 start to management could mean that early nesting oystercatchers, especially those that establish territories outside of historic areas would not be fully protected under alternative C.

Under alternative C, prenesting closures in SMAs would provide buffers around courting oystercatchers, Wilson's plover, and colonial waterbirds, which could have a beneficial effect. Under ML1, areas as closed to ORV and pedestrian access would reduce potential effects of bringing people, essential vehicles, and equipment into direct contact with state-listed/special status species and their habitat when compared to management under alternatives A and B. Under ML2 procedures, management of these areas would also reduce potential effects of vehicle collisions and disturbance by closing areas to ORV use; however, allowing a pedestrian corridor through the area combined with a reduction in buffer size for breeding, nesting, and unfledged chick activities would still bring people into direct contact with species.

With the designated SMA closures, ML1 and ML2 procedures and associated buffers for breeding/nesting/fledging areas, impacts from closures/buffers under alternative C would be long-term minor adverse.

*Wintering/Nonbreeding Management.* Nonbreeding surveys for American oystercatchers, Wilson's plover and red knots, would be conducted according to the NPS SECN survey protocol, although unlike alternatives A and B, surveys for some colonial waterbirds would be included. These surveying activities would have minor impacts (due to human disturbance as discussed above) and long-term benefits related to the increase in knowledge about the species.

Under alternative C, nonbreeding shorebird SMAs would be established for migrating/wintering shorebirds at various locations throughout the Seashore. Closures would be installed no later than when

breeding season closures are removed at the same location(s). Pets would be prohibited within Nonbreeding Shorebird SMAs. Nonbreeding resource closures would be established at the points and spits based on habitat used by wintering piping plovers in more than one of the past five years, the presence of birds at the beginning of the migratory season, and suitable habitat types based on the results of the annual habitat assessment. In addition to nonbreeding resource closures, NPS would establish VFAs along the ocean shoreline. This would ensure that adequate foraging, resting, and roosting areas would be provided for all migratory and nonbreeding state-listed/special status species compared to alternatives A and B, which do not have provisions to protect these nonbreeding species. Overall, management of species during nonbreeding would result in long-term beneficial impacts.

*Education and Outreach.* Under alternative C and as described under alternative B (including weekly resource and access reports, information on the Seashore website, and use of Google Earth), the public would continue to receive information at the visitor centers about state-listed/special status species and their ecology and the measures the Seashore is taking to protect the species. In addition, the public would be provided education through the required ORV use permit and protected species information would be provided at all access points. As with alternative A, public outreach as part of species management would have long-term beneficial impacts, with the expanded outreach having greater impacts than alternative A.

*Overall Impact of Resources Management Activities.* The overall impact of resources management activities (primarily resulting from the effects of surveying and field activities) for each species under alternative C would be as follows:

- American oystercatcher. Implementation of 10 SMAs that are closed to ORVs during the breeding season would provide a proactive resource closure early in the breeding season. Establishment of prenesting closures earlier in the season and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts related to human disturbance during field activities, on the whole, resources management activities would provide information that would enable the implementation of adaptive management initiatives and contribute to better management. These activities would result in long-term beneficial impacts to the American oystercatcher, greater than those provided under alternative B.
- Colonial waterbirds. Impacts to colonial waterbirds from surveying and field activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers.
- Wilson's plover. Impacts to Wilson's plover from surveying and field activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers, with slightly greater benefits as this species would also benefit from the management measures applied to piping plover.
- Red knot. Nonbreeding shorebird SMAs and the establishment of VFAs along the ocean shoreline would result in beneficial impacts to nonbreeding red knots. Many of the surveying and field activities would occur outside of the primary time when red knot are present at the Seashore. Therefore, any impacts to this species from surveying and field activities would be long-term negligible adverse. However, the ability of this species to use wintering closures that have been established for piping plover as well as the establishment of SMAs, some of which are closed to ORVs year-round, would be beneficial to those red knot that happen to use those areas, and overall result in long-term beneficial impacts to the species when compared to alternatives A and B.

### **ORV and Other Recreational Use**

*ORV and Pedestrian Access.* Under alternative C, approximately 27 miles of shoreline would be designated for ORV use year-round; approximately 27 miles would be designated for seasonal ORV use from October 15 through March 14; and approximately 13 miles would be designated as vehicle free year-round. The speed limit would be 15 mph unless otherwise posted and permits would be required for all ORVs. Three SMAs managed under ML2 procedures would maintain an open pedestrian access corridor, subject to resource closures, along the shoreline to the inlet or point.

The seasonal restrictions under alternative C would reduce the potential of disturbance and nest abandonment from direct short-term contact with people and/or essential vehicles compared to alternatives A and B, which would result in a beneficial impact. Although these measures should limit adverse impacts to state-listed/special status species, compliance with closures may not be absolute, since alternative C still includes pedestrian access to the three major points and spits during the summer season, and the areas that are closed to ORV over the rest of the Seashore are not expansive or contiguous. This could result in short-term minor to moderate adverse impacts if non-compliance occurs, but for the most part the populations would remain functional, and impacts limited to minor adverse by the restrictions extending through October 14 in all SMAs. Under alternative C, there would be seasonal ORV closures and recreational restrictions in key red knot habitat reducing the potential to impact resting and foraging red knots from vehicle use and associated noise and presence of people and pets.

As noted in chapter 3, a 3-year study on Cape Cod and Fire Island, New York (Kluft and Ginsberg 2009), found that higher ORV traffic resulted in dispersal and desiccation of the wrack line, thereby reducing the population of invertebrates in that area. Alternative C would allow for beach driving in the wrack during the day outside of SMAs, but would maintain nighttime closures and limit driving during the day where SMAs are established reducing disturbance in these areas. Overall impacts to invertebrates would be long-term and negligible to minor (as discussed later in this chapter), and would reduce the food source available to state-listed and special status species at the Seashore that rely on this food source, but to a lesser degree than if night driving was permitted, resulting in long-term minor impacts.

*Night-Driving Restrictions.* Under alternative C, all nonessential ORV traffic would be prohibited from all areas (other than the soundside) between 7:00 p.m. to 7:00 a.m. from May 1 to November 15. From November 16 to April 30, ORV use would be allowed 24 hours per day in designated ORV routes for vehicles holding a valid ORV permit. Furthermore, the NPS retains the discretion to limit night driving to certain areas or routes, based on resource protection considerations. Because these species are known to be active at night (Staine and Burger 1994; Majka and Shaffer 2008), chick and fledgling response to vehicles can increase their vulnerability to ORVs (USFWS 1996a, 2009a), the high level of protection at night from May 1 to November 15 under alternative C would result in long-term beneficial impacts because it would reduce the potential for disturbance to birds that could result in mortality, and would be more beneficial than alternative B because the restrictions start before dark.

*Commercial Fishing.* Management of commercial fishing vehicles would be the same as under alternative A and would be managed by the terms and conditions in the commercial fishing special use permit, which include restriction from entering resource closures. Commercial fisherman would not be required to obtain an ORV permit, but would be regulated under their existing commercial fishing special use permit. Under alternative C, commercial fishing vehicles would be authorized to enter VFAs except for full resource closures and lifeguarded beaches. Night-driving restrictions, which are applicable to all ORV use, could be slightly modified outside of existing resource closures for commercial fishing uses. Presence of commercial fishing operations would have a long-term negligible adverse impact on state-listed/special status species, with long-term minor to moderate benefits from night-driving restrictions.

*Permit/Carrying Capacity.* As described above under the night-driving restrictions and education/outreach sections, alternative C would require a permit for ORV use, which would include seasonal restrictions on night driving. As stated in these sections, the educational information provided by the required permit would result in benefits to state-listed/sensitive species as ORV users would be more aware of the regulations in place to protect these species, which would likely result in a higher level of compliance with these restrictions. There would be no impacts related to the implementation of a carrying capacity requirement under alternative C, as ORVs would not be permitted in resource protection areas.

*Pets/Other Recreational Activity Restrictions.* Pets would be prohibited within all designated Breeding Shorebird SMAs from March 15 to October 15 and within all Nonbreeding Shorebird SMAs that are otherwise open to recreational use. However, compliance would be needed to ensure that this reduces the risks of impacts. In addition, an educational permit would be required for any beach fire year-round, which would inform visitors about species protection issues related to this recreational use. Camping restrictions would be the same as alternative A, with additional requirements for removing beach equipment. These restrictions would result in long-term benefits to species at the Seashore, further reducing pressure to state-listed/special status species from recreational activity.

*Overall Impact of ORV and Other Recreational Use.* The overall impact of ORV and other recreational use for each species under alternative C would be as follows:

- American oystercatchers. Implementation of a permit system with an educational component, larger buffer sizes, seasonal night-driving restrictions, establishment of breeding and nonbreeding SMAs, and not allowing pets in SMAs would benefit the American oystercatcher. SMAs would provide a proactive method of limiting recreational uses early in the breeding season, and limit the potential for impacts to state-listed/special status species. However, alternative C does manage three SMAs under ML2 procedures, which provide for some level of pedestrian access into these areas and introduces the potential for impacts to the species. Although there would be some protection measures in place, ORV and other recreational use could still have impacts to the species, resulting in long-term minor to moderate adverse to American oystercatchers.
- Colonial waterbirds. Impacts to colonial waterbirds from ORV and other recreational use would be long-term minor to moderate adverse, for the same reasons as American oystercatchers under this alternative.
- Wilson's plover. Impacts to Wilson's plover from ORV and other recreational use would be long-term minor adverse, less than those under alternative A and B. Although this species would face the same adverse impacts as American oystercatchers and colonial waterbirds, it also tends to utilize the closures for piping plover, in addition to the specific buffers/closures provided for the species, and would therefore be provided slightly more protection than other state-listed/special status species.
- Red knot. Impacts to red knot from ORV and other recreational use would be long-term minor adverse due to the additional nonbreeding closures provided under alternative C that offer this wintering species further protection.

**Cumulative Impacts.** Cumulative actions and their associated impacts under alternative C would be the same as those described under alternatives A and B (long-term minor to moderate adverse). Although alternative C provides additional protection that would be beneficial to state-listed / special status bird species, the adverse effects on birds from other actions occurring in the region would still exist. The impact of these past, current, and reasonably foreseeable future actions, when combined with the long-term beneficial and long-term minor to moderate adverse impacts of alternative C, would result in long-term minor to moderate adverse cumulative impacts.

**Conclusion.** The overall impacts to state-listed/special status species under alternative C would be as follows:

- American oystercatcher. Establishment of prenesting closures earlier in the season and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts related to human disturbance during field activities, species surveying and field activities on the whole would provide information and result in actions that would be beneficial to the species. Implementation of SMAs that provide a proactive resource closure early in the breeding season, a permit system with an educational component, establishment of nonbreeding SMAs, seasonal night-driving restrictions, as well as larger buffer sizes and earlier prenesting closures, would provide long-term beneficial impacts to American oystercatchers, greater than those under alternative B. SMAs would provide a proactive method of limiting recreational uses early in the breeding season, and limit the potential for impacts to state-listed/special status species. However, alternative C does manage three SMAs under ML2 procedures, which provides for some level of pedestrian access into these areas, which introduces the potential for impacts to the species. Although there would be some protection measures in place, ORV and other recreational use could still have long-term minor to moderate adverse impacts to American oystercatchers.
- Colonial waterbirds. Impacts to colonial waterbirds from surveying and field activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers. Impacts to colonial waterbirds from ORV and other recreational use would be long-term minor to moderate adverse, for the same reasons as discussed for American oystercatchers under this alternative.
- Wilson's plover. Impacts to Wilson's plover from surveying and field activities would be long-term beneficial, for the same reasons as discussed above for the American oystercatcher, with slightly greater benefits as this species would also benefit from the management measures applied to piping plover. Impacts to Wilson's plover from ORV and other recreational use would be long-term minor adverse. Although this species would face the same adverse impacts as American oystercatchers and colonial waterbirds, it also tends to utilize the closures for piping plover, in addition to the specific buffers/closures provided for the species, and would therefore be provided slightly more protection than other state-listed/special status species.
- Red knot. Many of the surveying and field activities would occur outside of the primary time when red knot are present at the Seashore. Therefore, any impacts to this species from surveying and field activities would be long-term negligible adverse. However, the ability of this species to use wintering closures that have been established for piping plover as well as the establishment of both breeding and nonbreeding SMAs, some of which are closed to ORVs year-round, would be beneficial, and overall result in long-term beneficial impacts to the species when compared to alternatives A and B. Impacts to red knot from ORV and other recreational use would be long-term minor adverse due to the additional nonbreeding closures provided under alternative C that offer this wintering species further protection.

Cumulative impacts under alternative C would be long-term minor to moderate adverse.

## **Impacts of Alternative D: Increased Predictability and Simplified Management**

### **Resources Management Activities**

*Establishment of Prenesting Closures.* Under alternative D, as described under alternative C, the NPS would establish SMAs based on an annual habitat assessment for management of all breeding shorebirds

and subject to periodic review. All SMAs under alternative D would be managed under ML1 procedures during the breeding season (areas of larger, longer lasting buffers with less monitoring and closures to all ORV and pedestrian access) and would be closed year-round to ORV use. Under alternative D, breeding season closures of SMAs and the year-round prohibition of ORV in SMAs would have a long-term beneficial effect on all state-listed/special status species due to continual protection of all activities associated with shorebirds at the Seashore (breeding and nonbreeding) from ORV disturbance, and protection from pedestrian disturbance during the prenesting period. Establishment of these SMAs would have long-term beneficial impacts, which would be greater than those under alternatives A, B, or C, because of the size and duration of the closures, particularly when considering the year-round prohibition of ORV in these areas.

*Surveying and Monitoring.* Surveys of prenesting closures for all state-listed/special status species would occur three times per week. Surveys for American oystercatchers and Wilson's plovers would begin on March 15 and surveys for colonial waterbirds would begin on May 1. Surveys for suitable habitat outside of SMAs would also occur three times per week once breeding pairs are present.

Under ML1 procedures at all locations, the NPS would conduct nest surveys from a distance for American oystercatchers and Wilson's plover at least 3 times per week. Colonial waterbirds would also be observed at least three times per week from a distance that does not disturb the birds. Nest count estimates would be conducted during the peak nesting period for each species, which generally is during the last week of May and the first week of June, but could be later, especially for black skimmers. For all species that have incubating birds that cannot be observed from a distance, nest checks would occur on a weekly basis (or as staff is available). Colonial waterbird colonies would be surveyed for hatching (approximately 21 days after initial nest observations).

For unfledged chicks, the NPS would survey broods and colonies every other day. For American oystercatchers and Wilson's plover, observations end once chicks have fledged. For colonial waterbirds, a survey would be conducted during peak fledge (approximately 20 days after hatch counts). Observations would end after no unfledged chicks have been observed on three consecutive surveys. Under alternative D, as described under alternative C, surveys would concentrate in established SMAs, which may not detect American oystercatchers or colonial waterbirds that establish territories in new habitat.

Although surveying would provide substantial benefits to the species from data collected, surveying would bring people and/or essential vehicles into direct short-term contact with state-listed/special status species and their habitat, as described under alternative A. Therefore, under alternative D, species surveying could likely have long-term minor adverse impacts, from the introduction of human disturbance during these activities but overall surveying would provide long-term benefits to the species as it would allow the Seashore to better manage the species through the implementation of adaptive management initiatives. Many of the surveying and field activities would occur outside of the primary time when red knots are present at the Seashore. Therefore, any impacts to this species from surveying and field activities would be long-term negligible adverse.

As described under alternative C, surveying under alternative D would result in long-term beneficial impacts to state-listed/special status species.

*Buffer/Closure Establishment.* As described above, under alternative D, all SMAs would be managed under ML1 procedures. All 10 SMAs would be closed to ORV access year-round and would be closed pedestrian access and managed under ML1 procedures during the breeding season. Upon first observation of breeding activity, the standard buffers would apply. Buffers would be applied to courtship/mating, nesting, and unfledged chick activities both within and outside of designated SMAs. Under alternative D, as described under alternative C, ML1 procedures would maintain a 300-meter (900-foot) buffer during

all activities for all state-listed / special status bird species. For areas where breeding activity is observed outside of prenesting areas, ML1 procedures would apply to determine prescribed buffer distances. For alternative D, as described under alternative C, buffers would be removed outside of prenesting areas if no breeding activity is observed for a two-week period or when associated breeding activity has concluded, whichever is later. If breeding activity or scraping is observed outside of an existing closure, buffers would be expanded to accommodate the designated buffer under ML1 procedures. Under alternative D, as described under alternatives B and C, if NPS staff observe disturbance from ORVs and/or pedestrians, buffers would be expanded in 50-meter (164-foot) increments until no disturbance occurs. Also, for all species buffers/closures, vehicles and/or pedestrians may be allowed to pass through portions of the buffer or closures that are considered inaccessible to chicks because of steep topography, dense vegetation, or other naturally occurring obstacles.

Under alternative D, closure of SMAs to ORVs year-round and to pedestrians during the breeding season would result in a substantial beneficial effect to all state-listed/special status species and their habitat by eliminating potential effects of bringing people, essential vehicles, and equipment into direct contact with state-listed/special status species and their habitat when compared to management under alternatives A, B, and C. As described under alternatives A, B, and C, American oystercatchers at the Seashore can begin courting and nesting as early as mid-February or early March and be particularly sensitive to disturbance at that time (Cohen et al. 2010). Closure of SMAs to ORVs year-round and to pedestrians during the breeding season would ensure that early nesting American oystercatchers, except those that establish territories outside of areas that have not been utilized within the past five years, would be fully protected under alternative D. The year-round SMAs would provide long-term beneficial impacts to all state-listed/special status species at the Seashore.

Under alternative D, as described under alternatives A, B, and C, observations of chick movements may not be sufficient to adjust buffers such that they ensure protecting chicks from ORV/pedestrian impact; however, buffer/closure areas under alternative D would likely reduce any potential effects to negligible as many of the species would occur in the large SMAs. As described under alternatives A, B, and C, no additional buffers or closures would be provided to foraging adult state-listed/special status species under alternative D, although these species would likely indirectly benefit from the protections provided to piping plover foraging habitat and the large year-round SMAs.

Under alternative D, establishment of year-round SMAs managed under ML1 procedures during the breeding season, prenesting closures and increased buffer zones around breeding/nesting/fledging areas for all nesting state-listed/special status species and posting of nests with symbolic fencing, would not only eliminate ORV and reduce pedestrian use in historic bird use areas, but would also greatly reduce the possibility of disturbance to species (including first time breeders) and habitat compared to alternatives A, B, and C. With the designated SMA closures and implementation of buffers in areas not within closures, impacts from closures/buffers under alternative D would be long-term and beneficial to all breeding and nonbreeding state-listed / special status species by ensuring undisturbed nesting and wintering habitat.

*Wintering/Nonbreeding Management.* Nonbreeding surveys for American oystercatchers, Wilson's plover, red knots, and some species of colonial waterbirds would be conducted using the NPS SECN survey protocol. These surveying activities would have minor impacts due to disturbance from monitors, although the surveys would result in long-term benefits related to the increase in knowledge about the species and improvements in management methods.

Under alternative D, as described under alternative C, Nonbreeding Shorebird SMAs would be established for migrating/wintering shorebirds at various locations throughout the Seashore. Closures would be installed no later than when breeding season closures are removed at the same location(s). Pets would be prohibited within Nonbreeding Shorebird SMAs, although non-conflicting, nonmotorized

recreational uses would be allowed. Nonbreeding resource closures would be established at the points and spits. These nonbreeding SMAs would include areas of suitable nonbreeding habitat that has had concentrated foraging by migrating/wintering shorebirds in more than one (i.e., two or more) of the past five years and is managed to reduce human disturbance during the nonbreeding season. This may include portions of breeding SMAs that provide suitable nonbreeding habitat during periods of overlap between the breeding and migrating season and designated VFAs that are set aside to provide pedestrians with the opportunity for a natural beach experience. In addition to nonbreeding resource closures, the NPS would establish VFAs along the ocean shoreline. This would ensure that adequate foraging, resting, and roosting areas would be provided for all migratory and nonbreeding state-listed/special status species. Overall, management of species during nonbreeding would result in long-term beneficial impacts.

*Education and Outreach.* Under alternative D and as described under alternative A, the public would continue to receive information at the visitor centers about state-listed/special status species and their ecology and the measures the Seashore is taking to protect these species. In addition, the public would be provided education through the required ORV use permit, and protected species information would be provided at all access points. As with alternative A, public outreach as part of species management would have long-term beneficial impacts, with the expanded outreach having greater impacts than alternative A.

*Overall Impact of Resources Management Activities.* The overall impact of resources management activities (primarily resulting from the effects of surveying and field activities) for each species under alternative D would be as follows:

- American oystercatcher. Establishment of 10 SMAs that are closed to ORVs year-round and all managed under ML1 procedures during the breeding season would provide long-term benefits to breeding and wintering American oystercatchers, greater than those under alternative C. Additional benefits would be provided from surveying and closures outside of these established SMAs, as well as from the education and outreach provided. These surveying and field activities would provide information that would enable the implementation of adaptive management initiatives and contribute to better management. These activities would result in long-term beneficial impacts to this species, greater than those provided under alternative B.
- Colonial waterbirds. Impacts to colonial waterbirds from surveying and field activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers.
- Wilson's plover. Impacts to Wilson's plover from surveying and field activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers, with slightly greater benefits as this species would also benefit from the management measures applied to piping plover.
- Red knot. Nonbreeding shorebird SMAs and the establishment of VFAs along the ocean shoreline would result in beneficial impacts to nonbreeding red knots. Many of the surveying and field activities would occur outside of the primary time when red knot are present at the Seashore. Therefore, any impacts to this species from surveying and field activities would be long-term negligible adverse. However, the ability of this species to use wintering closures that have been established for piping plover as well as the establishment of SMAs, all of which are closed to ORVs year-round would result in long-term beneficial impacts to red knot when compared to all other alternatives.

### **ORV and Other Recreational Use**

*ORV and Pedestrian Access.* Under alternative D, approximately 27 miles of shoreline would be designated for ORV use and approximately 40 miles would be designated as vehicle free year-round.

There would be no seasonally designated ORV use areas. Compliance with closures would likely be easier for the public as the large SMAs areas would be clearly defined and predictable, and users would be educated as to where these areas are upon receiving an ORV use permit. Establishment of large, year-round SMAs that are managed under ML1 procedures during the breeding season, as well as educational information from a permit system, would provide a more defined separation of uses and reduced potential for recreational disturbance to birds than under alternatives A, B, or C. Impacts to state-listed and special status species from ORV and pedestrian access would be expected to be long-term minor adverse, as some interactions may still cause disturbance, but these events would likely be infrequent.

As noted in chapter 3, a 3-year study on Cape Cod and Fire Island, New York (Kluft and Ginsberg 2009), found that higher ORV traffic resulted in dispersal and desiccation of the wrack line, thereby reducing the population of invertebrates in that area. Alternative D would allow for beach driving in the wrack during the day outside of SMAs and would maintain nighttime closures. Restricting driving in SMAs year-round and seasonal night driving restrictions would reduce disturbance in these areas both seasonally and year-round. Compared to other alternatives, this alternative would also limit daytime ORV use in more areas of the Seashore. Overall impact to invertebrates would be long-term and negligible (as discussed later in this chapter), and would reduce the food source available to birds at the Seashore, but to a lesser degree than if night driving or greater access during the day was permitted, resulting in long-term negligible impacts to state-listed and special status species that rely on this food source.

*Night-Driving Restrictions.* Under alternative D, night driving of all nonessential ORV traffic would be the same as under alternative C and would result in long-term beneficial impacts as it would further reduce the potential for disturbance to night-foraging birds that could result in mortality.

*Commercial Fishing.* Commercial fishing activities under alternative D would be managed the same as under alternative C, resulting in long-term negligible adverse impacts to state-listed/special status species, with long-term minor to moderate benefits from night-driving restrictions.

*Permit/Carrying Capacity Requirements.* As described above under the night-driving restrictions and education/outreach sections, alternative D would require a permit for ORV use, which includes night driving. As stated in these sections, the educational information provided by the required permit would result in benefits to state-listed/sensitive species as ORV users would be more aware of the regulations in place to protect these species, which would likely result in a higher level of compliance. There would be no impacts related to carrying capacity, as ORV use would not be permitted in resource protection areas.

*Pets/Other Recreational Activity Requirements.* Pets would be prohibited within all SMAs year-round. Camping would not be permitted at the Seashore, and beach fires would be regulated with a non-fee educational permit, as described under alternative C. Prohibition of pets within the SMAs year-round and additional education from a beach fire permit would be expected to have long-term beneficial impacts to the species, greater than those under alternative C, provided the level of non-compliance is kept low.

*Overall Impact of ORV and Other Recreational Use.* The overall impact of ORV and other recreational use for each species under alternative D would be as follows:

- American oystercatcher. Providing large SMAs that are closed year-round to ORVs and closed to pedestrians during the breeding season would provide large undisturbed areas for both breeding and nonbreeding oystercatchers. Further benefits would be provided by seasonal night-driving restrictions, the establishment of a permit system with an educational component, and prohibition of pets in SMAs year-round. With these measures in place, impacts to American oystercatchers from ORV and other recreational use would be long-term minor adverse, as the chance of disturbance still exists, but would be lower than that under the other alternatives evaluated.

- Colonial waterbirds. Impacts to colonial waterbirds from ORV and other recreational use would be long-term minor adverse, for the same reasons as American oystercatchers under this alternative.
- Wilson's plover. Impacts to Wilson's plover from ORV and other recreational use would be long-term negligible to minor adverse. Although this species would face the same adverse impacts as American oystercatchers and colonial waterbirds, it also tends to utilize closures for piping plover, in addition to the buffers/closures provided specifically for this species, and would therefore be provided slightly more protection than other state-listed/special status species.
- Red knot. Impacts to red knot from recreation and other activities would be long-term negligible to minor adverse due to the additional nonbreeding closures provided under alternative D that offer this wintering species further protection, as well as the large year-round SMAs that would offer further protection during red knot wintering.

**Cumulative Impacts.** Cumulative actions and their associated impacts under alternative D would be the same as those described under alternative A (long-term minor to moderate adverse). Although alternative D provides additional protection that would be beneficial to state-listed / special status bird species, the adverse effects on birds from other actions occurring in the region would still exist. The impact of these past, current, and reasonably foreseeable future actions, when combined with the long-term beneficial and long-term negligible to minor adverse impacts of alternative D, would result in long-term minor adverse cumulative impacts.

**Conclusion.** Overall impacts to state-listed/special status species under alternative D would be as follows:

- American oystercatcher. Establishment of 10 SMAs that are closed year-round to ORVs and closed to pedestrians and managed under ML1 procedures during the breeding season would provide long-term benefits to breeding and wintering American oystercatchers. Additional benefits would be provided from surveying and closures outside of these established SMAs, as well as from the education and outreach provided. These surveying and field activities would all contribute to further knowledge about the species that would contribute to better management, and result in long-term beneficial impacts. Providing large SMAs that are closed to ORVs year-round and to pedestrians during the breeding season would provide the American oystercatcher a large undisturbed area for both breeding and nonbreeding. Further benefits would be provided by seasonal night-driving restrictions, prohibition of pets within SMAs, and the establishment of a permit system. With these measures in place, impacts to American oystercatchers from ORV and other recreational use would be long-term minor adverse, as the chance of disturbance still exists, but would be lower than that under the other alternatives evaluated.
- Colonial waterbirds. Impacts to colonial waterbirds from resources management activities would be long-term beneficial, for the same reasons as discussed above for the American oystercatcher. Impacts to colonial waterbirds from ORV and other recreational use would be long-term minor adverse, for the same reasons as American oystercatchers under this alternative.
- Wilson's plover. Impacts to Wilson's plover from resources management activities would be long-term beneficial, for the same reasons as discussed above for the American oystercatcher, with slightly greater benefits as this species would also benefit from the management measures applied to piping plover. Impacts to Wilson's plover from ORV and other recreational use would be long-term negligible to minor adverse. Although this species would face the same adverse impacts as American oystercatchers and colonial waterbirds, it also tends to utilize closures for piping plover, in addition to the specific buffers/closures provided for the species, and would therefore be provided slightly more protection than other state-listed/special status species.

- Red knot. Many of the surveying and field activities would occur outside of the primary time when red knot are present at the Seashore. Therefore, any impacts to this species from surveying and field activities would be long-term negligible adverse. However, the ability of this species to use wintering closures that have been established for piping plover as well as the establishment of SMAs, which are closed to ORVs year-round, would be beneficial, and overall result in long-term beneficial impacts to the species when compared to alternatives A and B. Impacts to red knot from ORV and other recreational use would be long-term negligible to minor adverse due to the additional nonbreeding closures provided under alternative D that offer this wintering species further protection, as well as the large year-round SMAs that would offer further protection during red knot wintering.

Cumulative impacts under alternative D would be long-term minor adverse.

## **Impacts of Alternative E: Variable Access and Maximum Management**

### **Resources Management Activities**

*Establishment of Prenesting Closures.* Under alternative E, as described under alternative C and D, the NPS would establish SMAs based on an annual habitat assessment for management of all breeding shorebirds and subject to periodic review. Seven SMAs would be managed under ML1 procedures and three under ML2 procedures. All Breeding Shorebird SMAs would be posted as prenesting closures using symbolic fencing by March 15 at sites involving American oystercatchers and Wilson's plover and by April 15 at sites involving colonial waterbirds. If multiple species exist on each site, closures would begin on the earliest date. Under alternative E, as described under alternative C, closure of prenesting areas by March 15 (in most cases) and/or April 15 for colonial waterbirds would have a more beneficial effect due to closures occurring earlier, ensuring a reduction of disturbance for colonial waterbirds during breeding (courtship, mating, scrapes, etc.).

*Surveying and Monitoring.* Surveys of prenesting closures for all state-listed/special status species would occur three times per week. Surveys for American oystercatchers and Wilson's plovers would begin on March 15 and surveys for colonial waterbirds would begin on May 1. Surveys for suitable habitat outside of SMAs would also occur 3 times per week once breeding pairs are present. Prenesting surveys under alternative E would not be as frequent as those under alternatives A and B; however, due to the designation of SMAs as prenesting closures and suitable habitat surveys outside of prenesting closures, effects of survey times to implement closures would be the same. Under alternative E, under ML1 procedures, less monitoring of nests would occur; however there would be no ORV or pedestrian access allowed. Under ML2 procedures, SMAs with this management would be monitored more frequently (the same as nesting areas under alternatives A and B) due to the presence of an ORV and/or pedestrian corridor.

Under ML1 procedures, NPS would conduct nest surveys from a distance for American oystercatchers and Wilson's plover at least three times per week. Colonial waterbirds would also be observed at least three times per week from a distance that does not disturb the birds. Nest count estimates would be conducted during the peak nesting period for each species, which generally is during the last week of May and the first week of June, but could be later, especially for black skimmers. For all species that have incubating birds that cannot be observed from a distance, nest checks would occur on a weekly basis (or as staff is available). Colonial waterbird colonies would be surveyed for hatching (approximately 21 days after initial nest observations). For unfledged chicks, NPS would survey broods and colonies every other day under ML1 procedures.

Under ML2 procedures, American oystercatcher and Wilson's plover chicks would be observed once daily for at least one-half hour and colonial waterbird colonies would be observed daily. For American oystercatchers and Wilson's plover, observations would end once chicks have fledged. For colonial waterbirds, a survey would be conducted during peak fledge (approximately 20 days after hatch counts). Observations would end after no unfledged chicks have been observed on three consecutive surveys.

Under alternative E, as described under alternatives C and D, surveys would concentrate in established SMAs, which may not detect American oystercatchers or colonial waterbirds that establish territories in new habitat. Surveying activities under alternative E would likely have long-term minor adverse impacts on nesting state-listed/special status species as a result of survey time and frequencies during the prenesting and nesting season at the Seashore. Although surveying can bring people into contact with the species and cause disturbance, overall species surveying would provide long-term beneficial impacts as it would provide the NPS with the information needed to implement adaptive management measures, and enhance future management. Many of the surveying and field activities would occur outside of the primary time when red knot are present at the Seashore. Therefore, any impacts to this species from surveying and field activities would be long-term negligible adverse.

*Buffer/Closure Establishment.* Under alternative E SMAs would be established and designated either ML1 or ML2. ML1 areas would not allow ORV or pedestrian access when prenesting closures are in effect. Bodie Island Spit, Cape Point, and South Point would be managed under ML2 procedures, and narrow ORV access corridors would be established in these areas. Upon first observation of breeding activity, the standard buffers would apply, which depending on the circumstances may close the access corridor. Pets, kite flying, ball and Frisbee tossing, or similar activities would be prohibited in access corridors while prenesting closures are in effect. If no breeding activity is observed in SMAs by July 31, or two weeks after all chicks have fledged (whichever is later), prenesting closures would be adjusted to the configurations of Nonbreeding Shorebird SMAs (as determined from annual monitoring of presence, abundance, and behavior of migrating and wintering shorebirds from July through May).

Under alternative E, a total of three SMAs would be closed to ORV access year-round. During the breeding season, a total of seven SMAs would be closed to ORV and pedestrian access under ML1 procedures areas from March 15 through August 31; and a total of three areas would be managed under ML2 procedures, which would allow an ORV access corridor with a pass-through zone from March 15 to August 31, subject to resource closures. Buffers would be applied to courtship/mating, nesting, and unfledged chick activities both within and outside of designated SMAs. Under ML1 procedures, a 300-meter (900-foot) buffer would be maintained during all activities for all state-listed / special status bird species. Under ML2 procedures, buffer areas would vary by species and activity. For ML2 procedures, buffers for American oystercatchers would be 150 meters (450 feet) for breeding and nesting activities and 200 meters (600 feet) for unfledged chick activity. ML2 buffers for least terns, a colonial waterbird, would be 100 meters (300 feet) for breeding and nesting activities and 200 meters (600 feet) for unfledged chick activity. All other colonial waterbird ML2 buffers would be 200 meters (600 feet) for breeding, nesting, and unfledged chick activities. For areas where breeding activity is observed outside of prenesting areas, buffers under ML1 would apply. For alternative E, buffers would be removed outside of prenesting areas if no breeding activity is observed for a two-week period or when associated breeding activity has concluded, whichever is later. If breeding activity or scraping is observed outside of an existing closure, buffers would be expanded to accommodate the designated buffer for that management level. Under alternative E, as described under alternatives B and C, if NPS staff observe disturbance from ORVs and/or pedestrians, buffers would be expanded in 50-meter (164-foot) increments until no disturbance occurs. Under alternative E, for all species buffers/closures, vehicles and/or pedestrians may be allowed to pass through portions of the buffer or closures that are considered inaccessible to chicks because of steep topography, dense vegetation, or other naturally occurring obstacles.

Under alternative E, closure of three SMAs year-round and prenesting closures in all SMAs would provide buffers around courting American oystercatchers, Wilson's plover, and colonial waterbirds, which could have a substantial beneficial effect. ML1 procedures that close areas to ORV and pedestrian access from March 15 to August 31 would reduce potential effects of bringing people, essential vehicles, and equipment into direct contact with state-listed/special status species and their habitat when compared to management under alternatives A and B; however the reduction of effects would not be as much as those under alternative C given the longer period of ORV closure under that alternative (October 14). Under ML2, the three SMAs that would have an ORV pass-through zone would have greater adverse impacts from disturbance than would occur in the three SMAs under alternative C that would have a pedestrian access corridor under ML2 procedures, due to the potential effects of vehicle collisions and disturbance from bringing people into direct contact with species.

Under alternative E, as described under alternatives A, B, and C, American oystercatchers at the Seashore can begin courting and nesting as early as mid-February or early March and be particularly sensitive to disturbance at that time (Cohen et al. 2010). Hence, a March 15 start to management could mean that early nesting oystercatchers, especially those that establish territories outside of historic areas would not be fully protected under alternatives A, B, C, or E.

Under alternative E, as described under alternatives A, B, and C, observations of chick movements may not be sufficient to adjust buffers such that they ensure protecting chicks from ORV/pedestrian impact; however, increased closure areas under alternative E would likely reduce any potential effects to negligible. As described under alternatives A, B, C, and D, no additional buffers or closures would be provided to foraging adult state-listed/special status species under alternative E, although species would likely indirectly benefit from the protections provided to piping plover foraging habitat.

Under alternative E, establishment of SMAs with ML1 and ML2 procedures, closure of some SMAs to ORV use year-round, increased buffer zones around breeding/nesting/fledging areas for all nesting state-listed/special status species, and posting of nests with symbolic fencing would reduce ORV and pedestrian use in multiple high use bird areas during sensitive timeframes, provide a major deterrent to the entry of people, pets, and ORVs into habitats, and greatly reduce the possibility of disturbance to species (including first time breeders) and habitat compared to alternatives A and B.

With the designated SMA closures, ML1 and ML2 procedures and associated buffers for breeding/nesting/fledging areas, impacts from closures/buffers under alternative E would be long-term minor adverse.

*Wintering/Nonbreeding Management.* Nonbreeding surveys for American oystercatchers, Wilson's plover and red knots, would be conducted according to the NPS SECN survey protocol, although unlike the no-action alternatives, surveys for some colonial waterbirds would be included. These surveying activities would have minor impacts (due to human disturbance as discussed above) and long-term benefits related to the increase in knowledge about the species. Surveying activities would have negligible impacts to red knots during the breeding season (for other state-listed/special status species) at the Seashore, and long-term benefits related to the increase in knowledge about the species resulting from nonbreeding surveys.

Under alternative E, as described under alternatives C and D, Nonbreeding Shorebird SMAs would be established for migrating/wintering shorebirds at various locations throughout the Seashore. Closures would be installed no later than when breeding season closures are removed at the same location(s). Pets would be prohibited within Nonbreeding Shorebird SMAs. These nonbreeding SMAs would include areas of suitable nonbreeding habitat that has had concentrated foraging by migrating/wintering shorebirds in more than one (i.e., two or more) of the past five years and is managed to reduce human disturbance during the nonbreeding season. This may include portions of breeding SMAs that provide suitable

nonbreeding habitat during periods of overlap between the breeding and migrating season and designated VFAs that are set aside to provide pedestrians with the opportunity for a natural beach experience. In addition to nonbreeding resource closures, the NPS would establish VFAs along the ocean shoreline. This would ensure that adequate foraging, resting, and roosting areas would be provided for all migratory and nonbreeding state-listed/special status species. Management of wintering/nonbreeding populations would provide long-term benefits, but these benefits would not be as great as those under alternative D, as alternative E would provide an increased level of recreational access and therefore an increased potential for disturbance to state-listed/special status species.

*Education and Outreach.* Under alternative E, impacts as a result of education and outreach efforts, including educational information from a required ORV permit, would be long-term and beneficial, as described under alternative C.

*Overall Impact of Resources Management Activities.* The overall impact of resources management activities (primarily resulting from the effects of surveying and field activities) for each species under alternative E would be as follows:

- American oystercatcher. Implementation of 10 SMAs, 7 of which are closed to ORVs during the breeding season, would provide a proactive resource closure early in the breeding season. Establishment of prenesting closures earlier in the season and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts from human disturbance during field activities, resources management activities on the whole would provide information that would enable the implementation of adaptive management initiatives and contribute to better management. These activities would result in long-term beneficial impacts to this species, greater than those provided under alternative B.
- Colonial waterbirds. Impacts to colonial waterbirds from resources management activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers.
- Wilson's plover. Impacts to Wilson's plover from resources management activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers, with slightly greater benefits as this species would also benefit from the management measures applied to piping plover.
- Red knot. Many of the surveying and field activities would occur outside of the primary time when red knot are present at the Seashore. Therefore, any impacts to this species from surveying and field activities would be long-term negligible adverse. However, the ability of this species to use wintering closures that have been established for piping plover as well as the establishment of SMAs, some of which are closed year-round, would be beneficial, and overall result in long-term beneficial impacts to the species when compared to alternatives A and B.

### **ORV and Other Recreational Use**

*ORV and Pedestrian Access.* Under alternative E, approximately 32 miles of shoreline would be designated for ORV use year-round; approximately 20 miles would be seasonally designated for ORV use from September 1 through March 14; and approximately 16 miles would be designated as vehicle free year-round. The speed limit would be 15 mph unless otherwise posted, and permits would be required for all ORVs. Three SMAs (under ML2 procedures) would maintain an ORV corridor with a pass-through zone from March 15 to August 31, subject to resource closures.

Management of ORV and pedestrian access under alternative E would reduce the potential for disturbance and nest abandonment from direct contact with people and vehicles compared to alternatives A and B, but would have greater impacts than alternative C as a result of the increased amount of recreational access provided by the establishment of an ORV corridor in areas under ML2 procedures and a reduction in the length of closure in areas under ML1 procedures from October 14 under alternative C to August 31. Adverse impacts would also be greater under alternative E than alternative D, which has all SMAs closed to ORVs year-round and closed to pedestrian use during the breeding season. As described under alternative C, these measures should limit adverse impacts to state-listed / special status species; however, compliance with closures may not be absolute, resulting in adverse impacts if non-compliance occurs, but for the most part the populations would remain functional and adverse impacts limited in the SMAs by the seasonal or year-round restrictions.

Under alternative E, there would be seasonal closures in key red knot habitat reducing the potential to impact resting and foraging red knots from vehicle use and associated noise and presence of people and pets.

As noted in chapter 3, a 3-year study on Cape Cod and Fire Island, New York (Kluft and Ginsberg 2009), found that higher ORV traffic resulted in dispersal and desiccation of the wrack line, thereby reducing the population of invertebrates in that area. Alternative E would allow for beach driving in the wrack during the day outside of SMAs but would maintain nighttime closures and limit driving during the day where SMAs are established reducing disturbance in these areas. Overall impacts to invertebrates would be long-term and minor (discussed later in this chapter), and would reduce the food source available to state-listed and special status species at the Seashore that rely on this food source, but to a lesser degree than if night driving was permitted, resulting in long-term minor impacts.

Overall, there would be long-term minor to moderate adverse impacts to nesting state-listed/special status species from ORV and pedestrian access under alternative E as providing more areas managed under ML2 procedures during the breeding season would result in more recreational access and an increased chance of species disturbance. Impacts to nonbreeding red knots would be long-term minor adverse.

*Night-Driving Restrictions.* Under alternative E, night-driving restrictions for all nonessential ORV traffic would be similar to alternative B. American oystercatchers, Wilson's plover, and red knot are known to be active at night (Simons and Schulte 2008; Morrier and McNeil 1991; Niles et al. 2007), and would be subject to disturbance from vehicular and pedestrian disturbance. This disturbance can impact their foraging behavior and has been shown to result in disorientation and even abandonment of American oystercatcher chicks (Simons and Schulte 2008). Restrictions on night driving under alternative E would provide long-term benefits to state-listed/special status species; however, night driving could still result in long-term minor adverse impacts during the time when night driving is allowed by permit. Further, night-driving restrictions that begin after dark, in this case 10:00 p.m., do not offer full nighttime protection to the species.

*Commercial Fishing.* Management of commercial fishing under alternative E would be the same as alternative C, resulting in long-term negligible adverse impacts from the presence of commercial fishing vehicles, with long-term minor to moderate benefits from night-driving restrictions.

*Permit/Carrying Capacity.* As described above under the night-driving restrictions and education/outreach sections, alternative E would require a permit for ORV use, which would include night driving. As stated in these sections, the educational information provided by the required permit would result in benefits to state-listed/sensitive species as ORV users would be more aware of the regulations in place to protect these species, which would likely result in a higher level of compliance.

There would be no impacts related to the implementation of a carrying capacity requirement under alternative E, because ORVs would not be permitted within resource protection areas.

*Pets/Other Recreational Activity Restrictions.* Pets would be prohibited within all SMAs, as described under alternative C. This would include the ORV pass-through zones under alternative E and the seasonal prohibition dates would be March 15 to August 31. As with alternative C, an educational permit would be required for any beach fire year-round, which would inform visitors about species protection issues related to this recreational use.

Camping restrictions would be the same as alternative C; however, the Seashore would issue park-and-stay permits for overnight beach use at selected spits and points that are not closed for resource protection. The provision for park-and-stay overnight at some spits and points during portions of the breeding season when resource closures do not preclude access would increase the potential for human disturbance to breeding and nesting birds adjacent to those locations.

Overall, restrictions on pets, camping, and beach fires would result in long-term benefits to species at the Seashore, further reducing pressure to state-listed/special status species from recreational activity, with the potential for long-term minor to moderate adverse impacts from the park-and-stay option, which would occur outside of resource closures.

*Overall Impact of ORV and Other Recreational Use.* The overall impact of ORV and other recreational use for each species under alternative E would be as follows:

- American oystercatcher. Implementation of a permit system with an educational component, larger buffer sizes, seasonal night-driving restrictions, restrictions on pets in SMAs, and establishment of breeding and nonbreeding SMAs would benefit the American oystercatcher. SMAs would provide a proactive method of limiting recreational uses early in the breeding season, and limit the potential for impacts to state-listed/special status species. However, alternative E does allow an ORV access corridor at three SMAs managed under ML2 procedures during the breeding season (more than the other action alternatives), which provide for some level of pedestrian or ORV access into these area, which introduces the potential for impacts to the species. Although there would be some protection measures in place, recreational use could still result in long-term minor to moderate adverse impacts to American oystercatchers.
- Colonial waterbirds. Impacts to colonial waterbirds from ORV and other recreational use would be long-term minor to moderate adverse, for the same reasons as those discussed above for American oystercatchers under this alternative.
- Wilson's plover. Impacts to Wilson's plover from ORV and other recreational use would be long-term minor adverse. Although this species would face the same adverse impacts as American oystercatchers and colonial waterbirds, it also tends to utilize closures for piping plover, in addition to the buffers/closures provided specifically for this species, and would therefore be provided slightly more protection than other state-listed/special status species.
- Red knot. Impacts to red knot from ORV and other recreational use would be long-term minor adverse due to the additional nonbreeding closures provided under alternative E that offer this wintering species further protection; however, there would be greater adverse impacts than under alternatives D or F due to fewer miles of shoreline being closed to ORVs under alternative E during the nonbreeding season.

**Cumulative Impacts.** Cumulative actions and their associated impacts under alternative E would be the same as those described under alternatives A, B, C, and D (long-term minor to moderate adverse).

Although alternative E provides additional protection which would be beneficial to state-listed / special status bird species, the adverse effects on birds from other actions occurring in the region would still exist. The impact of these past, current, and reasonably foreseeable future actions would be minor adverse. These impacts, when combined with the long-term beneficial and long-term minor to moderate adverse impacts of alternative E, would have long-term minor to moderate cumulative impacts.

**Conclusion.** Overall impacts to state-listed/special status species under alternative E would be as follows:

- American oystercatcher. Establishment of prenesting closures earlier in the season and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts related to human disturbance during field activities, resource management activities on the whole would provide information and result in actions that would be beneficial to the species. Implementation of SMAs that provide a proactive resource closures early in the breeding season, a permit system with an educational component, seasonal night-driving restrictions, as well as larger buffer sizes and earlier prenesting closures, would provide long-term beneficial impacts to the American oystercatcher, greater than those under alternative B. Implementation of a permit system with an educational component, seasonal night-driving restrictions, prohibition of pets in the SMAs during breeding season, and establishment of breeding and nonbreeding SMAs would benefit the American oystercatcher. SMAs would provide a proactive method of limiting recreational uses early in the breeding season, and limit the potential for impacts to state-listed/special status species. However, alternative E does allow ORV access to three SMAs that would be managed under ML2 procedures during the breeding season (more than the other action alternatives), which provide for some level of pedestrian or ORV access into these area and which introduces the potential for impacts to the species. Although there would be some protection measures in place, recreational use could still result in long-term minor to moderate adverse impacts to American oystercatchers.
- Colonial waterbirds. Impacts to colonial waterbirds from resources management activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers. Impacts to colonial waterbirds from ORV and other recreation use would be long-term minor to moderate adverse, for the same reasons as American oystercatchers under this alternative.
- Wilson's plover. Impacts to Wilson's plover from resources management activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers, with slightly greater benefits as this species would also benefit from the management measures applied to piping plover. Impacts to Wilson's plover from ORV and other recreational use would be long-term minor adverse. Although this species would face the same adverse impacts as American oystercatchers and colonial waterbirds, it also tends to utilize closures for piping plover, in addition to closures/buffers provided specifically for this species, and would therefore be provided slightly more protection than other state-listed/special status species.
- Red knot. Many of the surveying and field activities would occur outside of the primary time when red knot are present at the Seashore. Therefore, any impacts to this species from surveying and field activities would be long-term negligible adverse. However, the ability of this species to use wintering closures that have been established for piping plover as well as the establishment of SMAs, some of which are closed to ORVs year-round, would be beneficial, and overall result in long-term beneficial impacts to the species when compared to alternatives A and B. Impacts to red knot from ORV and other recreational use would be long-term minor adverse due to the additional nonbreeding closures provided under alternative E that offer this wintering species further protection, with greater adverse impacts than under alternatives D or F from fewer miles of shoreline being closed to ORVs under alternative E during the nonbreeding season.

Cumulative impacts under alternative E would be long-term minor to moderate adverse.

## **Impacts of Alternative F: NPS Preferred Alternative**

### **Resources Management Activities**

*Establishment of Prenesting Closures.* Under alternative F, a survey for potential breeding habitat would occur by March 1 (except for colonial waterbirds, which would occur by April 1) and prenesting closures would be established using symbolic fencing by March 15 at sites involving American oystercatchers and Wilson's plover and by April 15 at sites involving colonial waterbirds. If multiple species exist on each site, closures would begin on the earliest date. Establishment of closures early in the season would have long-term beneficial impacts to these species.

SMA's would not be established, as described under alternatives C, D, and E. Instead, prenesting closures for American oystercatcher, Wilson's plover, and colonial waterbirds would be established and areas of known breeding habitat, such as Bodie Island, would be designated as seasonal or year-round VFAs. These areas would be open to pedestrians but subject to resource closures as described in table 10-1, providing areas of relatively less disturbance; however, there would be more disturbance under this alternative in prenesting areas, as pedestrians would be permitted seaward of prenesting closures, unless breeding activity is present and a resource closure is necessary. Once established in the beginning of the breeding season, these areas would not be reduced to accommodate an ORV corridor. Under alternative F, all areas of the Seashore would be managed similar to the ML2 procedures described for alternatives C, D, and E (see table 10-1).

*Surveying and Monitoring.* Surveys of prenesting closures for all state-listed/special status species would occur three times per week. Surveys for American oystercatchers and Wilson's plover would begin on March 15 and surveys for colonial waterbirds would begin on May 1. Surveys for suitable habitat would also occur three times per week outside prenesting closures once breeding pairs are present. Many of the surveying and field activities would occur outside of the primary time when red knot are present at the Seashore. Therefore, any impacts to this species from surveying and field activities would be long-term negligible adverse.

The NPS would observe American oystercatcher nests/scrapes from a distance on a daily basis and Wilson's plover nests/scrapes every three days. Colonial waterbird scrapes/nests would also be observed daily from a distance that does not disturb the birds. Colonial waterbird nest count estimates would be conducted during the peak nesting period for each species, which generally is during the last week of May and the first week of June, but could be later, especially for black skimmers. For all species that have incubating birds that cannot be observed from a distance, nest checks would occur every three days. For unfledged chicks, NPS would observe broods and colonies once daily for Wilson's plover, American oystercatcher, and colonial waterbirds. For American oystercatchers, if the brood cannot be located, at least one-half hour would be spent in efforts to locate the brood/chick. Colonial waterbird colonies would be surveyed for unfledged chicks during the peak hatching period (approximately 21 days after initial nest observations).

For American oystercatchers and Wilson's plover, observations end once chicks have fledged. For colonial waterbirds, a survey would be conducted during peak fledge (approximately 20 days after hatch counts). Observations would end after no unfledged chicks have been observed on three consecutive surveys. As described under all other alternatives, surveying under alternative F would provide benefits to the species.

Under alternative F surveys would concentrate in established prenesting closures, which may not detect American oystercatchers or colonial waterbirds that establish territories in new habitat. As described under all other alternatives, surveying under alternative F would provide benefits to the species.

Under alternative F, as described under alternative B, C, and E, closure of prenesting areas by March 15 (in most cases) and/or April 15 for colonial waterbirds would have a more beneficial effect due to closures occurring earlier, ensuring a reduction of disturbance for colonial waterbirds during breeding (courtship, mating, scrapes, etc.) than under alternative A. Prenesting surveys under alternative F would not be as frequent as those under alternatives A and B; however, due to the designation of prenesting closures within suitable habitat, established buffers for breeding activity, as well as the designation of seasonal and year-round VFAs in locations of known habitat, effects of survey times to implement closures would be the same. Under alternative F, management of all areas of the Seashore would be similar to the ML2 procedures described under alternatives C, D, and E and would require more frequent monitoring (the same as nesting areas under alternatives A and B) due to the presence of ORVs and/or pedestrians in these areas. Alternative F would likely have minor adverse impacts on nesting state-listed/special status species from survey time and frequencies during the prenesting and nesting season at the Seashore, but overall the information provided would allow the Seashore to implement adaptive management initiatives, thereby improving future management, resulting in overall long-term beneficial impacts.

*Buffer/Closure Establishment.* Under alternative F, all areas of the Seashore would be managed in a way similar to the ML2 procedures detailed under alternatives C, D, and E, but would provide for prenesting closures instead of SMAs. Outside of prenesting closures, buffers would be established based on breeding/nesting activity (see table 10-1). Under alternative F, areas of the Seashore would be designated as vehicle free seasonally or year-round including:

- Ramp 1 to 0.5 miles south of Coquina Beach (year-round)
- 0.2 mile south of ramp 4 to southeast corner of Bodie Island spit (vehicle free March 15 to September 14)
- Southeast corner of Bodie Island spit along inlet shoreline to southwest edge of Bait Pond (near bridge) (year-round)
- Rodanthe boundary to 0.1 mile south of Rodanthe pier (year-round)
- 0.1 mile south of Rodanthe Pier–Waves–Salvo to ramp 23 (vehicle free April 1 to October 31)
- Ramp 23 to 1.5 miles south of ramp 23 (year-round)
- Ramp 27 to ramp 30 (year-round)
- Ramp 32.5 to ramp 34 (year-round)
- Ramp 34 to ramp 38 (vehicle free April 1 to October 31)
- Ramp 38 to 1.5 miles south of ramp 38 (i.e., Haulover) (year-round)
- 0.3 mile west of the hook (Cape Point) to 1.7 miles west of ramp 45 (year-round)
- Frisco Village Beach (east village boundary to west boundary) (vehicle free April 1 to October 31)
- Sandy Bay / Frisco day use area (west Frisco boundary to east Hatteras Village boundary) (year-round)
- Hatteras Village Beach (east boundary to ramp 55) (vehicle free April 1 to October 31)

- Bone Road to Hatteras Inlet, along inlet shoreline to Spur Road (year-round)
- (New) interdunal road from eastern portion of Spur Road west toward inlet (vehicle free March 15 to September 14)
- Hatteras Inlet to (new) ramp 59.5 (year-round)
- (New) ramp 63 to 1.0 mile northeast of ramp 67 (year-round)
- 0.5 mile northeast of ramp 68 to ramp 68 (Ocracoke Campground area) (vehicle free April 1 to October 31)
- Ramp 68 to 0.4 miles northeast of ramp 70 (includes Ocracoke Day Use area) (year-round).

Pedestrians would be permitted in VFAs, but these areas would be subject to resource closures, following the procedures outlined in table 10-1. Within both ORV areas and VFAs, surveys for potential habitat would occur, as described above, and prenesting closures would be established. Prenesting closures for Wilson's plover and American oystercatchers would begin on March 15 and for colonial waterbirds on May 1. If no breeding activity is seen, these prenesting closures would be removed July 15 (or August 15 if black skimmers are present), or two weeks after all chicks have fledged.

At Cape Point and South Point, an ORV corridor would be established, but would be reduced in size from 50 meters (164 feet) during the nonbreeding season to 35 meters (115 feet) during prenesting and breeding seasons. Upon first observation of breeding activity, the standard buffers would apply, which depending on the circumstances may close access corridors. Once breeding activity has ceased, the corridor would return to 50 meters (164 feet).

Under alternative F, buffers would be applied to courtship/mating, nesting, and unfledged chick activities throughout the Seashore, in both designated ORV routes and VFAs. Buffers for American oystercatchers would be 150 meters (450 feet) for breeding and nesting activities and 200 meters (600 feet) for unfledged chick activity. Buffers for Wilson's plover would be 75 meters (246 feet) for breeding and nesting activities and 200 meters (600 feet) for unfledged chick activity. Under alternative F, buffers for least terns, a colonial waterbird, would be 100 meters (300 feet) for breeding and nesting activities and 200 meters (600 feet) for unfledged chick activity. All other colonial waterbird buffers would be 200 meters (600 feet) for breeding, nesting, and unfledged chick activities.

For all species, the Seashore would retain the discretion to expand scrape or nest buffers as needed to protect resources. In unprotected areas, a buffer would be established immediately when a nest with egg(s) is found. If breeding activity or scraping is observed outside of an existing closure, buffers would be expanded to accommodate the designated buffer for the particular species. Prior to hatching, vehicles may be allowed to pass by such areas within designated ORV access corridors that have been established along the outside edge of nesting habitat where, in the judgment of Seashore resources management staff, steep topography, dense vegetation, or other naturally-occurring obstacles minimize the risk of human disturbance. Such sites would be re-evaluated for disturbance during each subsequent survey. When scrape(s), nest(s), or chick(s) occur in the immediate vicinity of paved roads, parking lots, campgrounds, buildings, and other facilities, such as within the villages or at NPS developed sites, the NPS would retain the discretion to provide resource protection to the extent possible while still allowing those facilities to remain operational. Regardless of the nature of the adjacent facilities, in all cases, as a minimum, NPS would provide signs, fencing and reduced buffers to protect nest(s) and chick(s) once they occur.

The NPS would not reduce buffers to accommodate an ORV corridor or ORV ramp access. Buffers would remain in place for two weeks after a nest is lost to determine if the pair will re-nest. For buffers that occur outside of, or that expand, the original prenesting areas, the buffer or expansion would be

removed if no breeding activity is observed for a two-week period, or when associated breeding activity has concluded, whichever is later.

If breeding activity or scraping is observed outside of an existing closure, buffers would be expanded to accommodate the designated buffer for that species, as detailed in table 10-1. Under alternative F, as described under alternatives B through E, if NPS staff observe disturbance from ORVs and/or pedestrians, buffers would be expanded in 50-meter (164-foot) increments until no disturbance occurs. Under alternative F, for all species buffers/closures, vehicles and/or pedestrians may be allowed to pass through portions of the buffer or closures that are considered inaccessible to chicks because of steep topography, dense vegetation, or other naturally occurring obstacles.

Under alternative F, the prenesting closures would provide a buffer around courting oystercatchers, Wilson's plovers, and colonial waterbirds, and the buffers detailed in table 10-1 would provide additional protections during breeding/nesting activities. The seasonal or year-round VFAs, as described above would also provide areas of less disturbance due to the absence of ORVs. These measures together could have a beneficial effect. Prenesting areas closed to ORV and pedestrian access from March 15 to July 31 or two weeks after all chicks have fledged, whichever is later, would reduce potential effects of bringing people, essential vehicles, and equipment into direct contact with state-listed/special status species and their habitat when compared to management under alternatives A and B. However, the reduction of effects would be greater at some locations under alternative F as many of the VFAs are year-round, and many are seasonally vehicle free until October 31 (or September 15 at two locations). These seasonal VFAs are also longer than alternatives C or E, which have seasonal VFAs of shorter duration (October 14 and August 31 respectively).

American oystercatchers at the Seashore can begin courting and nesting as early as mid-February or early March and be particularly sensitive to disturbance at that time (Cohen et al. 2010). Hence, a March 15 start to management could mean that early nesting oystercatchers, especially those that establish territories outside of historic areas, would not be fully protected under alternatives A, B, C, E, or F.

Under alternative F, as described under alternatives A, B, C, and E, observations of chick movements may not be sufficient to adjust buffers such that they ensure protecting chicks from ORV/pedestrian impact; however, increased closure areas under alternative F would likely reduce any potential effects to negligible. As described under all of the other alternatives, no additional buffers or closures would be provided to foraging adult state-listed/special status species under alternative F, although species would likely indirectly benefit from the protections provided to piping plover foraging habitat.

Under alternative F, establishment of prenesting closures and seasonal or year-round VFAs; increased buffer zones around breeding/nesting/fledging areas for all nesting state-listed/special status species; and posting of nests with symbolic fencing, would not only eliminate or significantly reduce ORV and pedestrian use in multiple high use bird areas during sensitive timeframes, but would also provide a major deterrent to the entry of people, pets, and ORVs into habitats and greatly reduce the possibility of disturbance to species (including first time breeders) and habitat compared to alternatives A and B. Overall reduction of effects would be greater under alternative F than those under alternatives C and E due to the seasonal and year-round VFAs. The potential for disturbance would be minimized, in part, as breeding areas would not reopen to recreational use until after all chicks in an area have fledged, which could be after July 31 depending upon the species.

With the designated prenesting closures, VFAs, and associated buffers for breeding/nesting/fledging areas, impacts to state-listed/special status species as a result of the buffers and closures provided under alternative F would be long-term minor adverse.

*Wintering/Nonbreeding Management.* Nonbreeding surveys for American oystercatchers, Wilson's plover and red knots, would be conducted, although unlike the no-action alternatives, surveys for some colonial waterbirds would be included. These surveying activities would have minor impacts (due to human disturbance as discussed above) and long-term benefits related to the increase in knowledge about the species.

Under alternative F, an annual habitat assessment would be conducted after all of the birds have fledged from the area. Prior to removing prenesting closures, resource closures would be established in the most sensitive portions of nonbreeding shorebird habitat at the points and spits, based on habitat used by piping plovers in more than one (i.e., two or more) of the past five years. Other species would be able to take advantage of the closures that are based on piping plover behavior. No people or pets would be permitted in these closures. Additional protection for nonbreeding birds, including Wilson's plover, American oystercatcher, red knots, and colonial waterbirds, would be provided by the year-round VFAs under alternative F that would provide a relatively less disturbed area for foraging, resting and roosting for migrating and wintering birds. These areas would be open to pedestrians for recreational use, and pets would be permitted under the provisions of 36 CFR 2.15, which applies to all units of the national park system and prohibits pet owners from "failing to crate, cage, restrain on a leash which shall not exceed 6 feet in length, or otherwise physically confine a pet at all times." These nonbreeding closures and VFAs would provide long-term benefits under alternative F, with these benefits being greater than alternatives C and E due to the additional year-round VFAs.

*Education and Outreach.* Under alternative F, the public would continue to receive information at the visitor centers about state-listed/special status species and their ecology and the measures the Seashore is taking to protect the species. In addition, the public would be provided education through the required ORV use permit and protected species information would be provided at all access points. As with alternative A, public outreach as part of species management would have long-term beneficial impacts, with the expanded outreach having greater impacts than alternative A.

*Overall Impact of Resources Management Activities.* The overall impact of resources management activities (primarily resulting from the effects of surveying and field activities) for each species under alternative F would be as follows:

- American oystercatcher. Implementation of prenesting closures, buffers for breeding/nesting, and year-round and seasonal VFAs would provide a proactive resource closure early in the breeding season. Establishment of prenesting closures earlier in the season and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts related to human disturbance during field activities, resources management activities on the whole would provide information that would enable the implementation of adaptive management initiatives and contribute to better management. These activities would result in long-term beneficial impacts to the species, greater than those provided under alternative B.
- Colonial waterbirds. Impacts to colonial waterbirds from resources management activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers.
- Wilson's plover. Impacts to Wilson's plover from resources management activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers, with slightly greater benefits as this species would also benefit from the management measures applied to piping plover.
- Red knot. Many of the surveying and field activities would occur outside of the primary time when red knot are present at the Seashore. Therefore, any impacts to this species from surveying

and field activities would be long-term negligible adverse. However, the ability of this species to use wintering closures that have been established for piping plover as well as the establishment of year-round VFAs, would be beneficial, and overall result in long-term beneficial impacts to the species when compared to alternatives A and B.

### **ORV and Other Recreational Use**

*ORV and Pedestrian Access.* Under alternative F, approximately 28 miles of shoreline would be designated for ORVs use year-round; approximately 13 miles would be seasonally designated for ORV use from either November 1 through March 31 or September 15 through March 14; and approximately 26 miles would be designated as vehicle free year-round. The speed limit would be 15 mph unless otherwise posted and permits would be required for all ORVs. An ORV corridor would be maintained at Cape Point and South Point once prenesting closures are established, but would be reduced in size and would be subject to resource closures.

Management of ORV and pedestrian access under alternative F would reduce the potential of disturbance and nest abandonment from direct short-term contact with people and/or essential vehicles compared to alternatives A and B. Compared to alternatives C and E, it would also have less impacts because of the year-round and seasonal VFAs, and the reduced size of the ORV corridor, that is subject to resource closures, at Cape Point and South Point. Impacts would be greater under alternative F than alternative D, which has all SMAs closed to ORVs year-round and closed to pedestrian use during the breeding season, a greater area than the VFAs under alternative F. As described under all of other alternatives, all measures taken for species protection, including buffers and monitoring, should limit adverse impacts to state-listed/special status species; however, compliance with closures may not be absolute, resulting in short-term moderate to major adverse impacts if non-compliance occurs. However, for the most part, the populations would be remain functional and impacts limited to minor to moderate adverse due to the buffers in place from prenesting and resource closures, as well as the year-round or seasonal VFAs that provide areas with less disturbance.

Under alternative F, there would be seasonal closures in key red knot habitat, as well as more year-round VFAs, reducing the potential to impact resting and foraging red knots from vehicle use and associated noise and presence of people and pets, offering greater protection to this species than alternatives A, B, C, or E.

As noted in chapter 3, a 3-year study on Cape Cod and Fire Island, New York (Kluft and Ginsberg 2009), found that higher ORV traffic resulted in dispersal and desiccation of the wrack line, thereby reducing the population of invertebrates in that area. Alternative F would allow for beach driving in the wrack during the day on ORV routes outside of designated VFAs and would maintain nighttime closures. These measures would reduce disturbance in these areas both seasonally and year-round. Overall impacts to invertebrates would be long-term and minor (as discussed later in this chapter), and would reduce the food source available to state-listed and special status species at the Seashore that rely on this food source, but to a lesser degree than if night driving was permitted, resulting in long-term minor impacts.

Overall, there would be long-term minor to moderate adverse impacts to nesting state-listed/special status species, and long-term minor adverse impacts to red knot from ORV and pedestrian access under alternative F.

*Night-Driving Restrictions.* Under alternative F, all nonessential ORV traffic would be prohibited from all areas (other than the soundside), from 9:00 p.m. to 7:00 a.m. from May 1 to November 15. From September 16 to November 15, ORV routes with no turtle nests remaining would reopen for night driving subject to the terms and conditions of the standard ORV permit. From November 16 to April 30, ORV

use would be allowed 24 hours per day in designated ORV routes for vehicles with a valid ORV permit. Furthermore, the NPS retains the discretion to limit night driving to certain areas or routes, based on resource protection considerations. Because some species are known to be active at night (Staine and Burger 1994; Majka and Shaffer 2008), and chick and fledgling response to vehicles can increase their vulnerability to ORVs (USFWS 1996a), the high level of protection at night from May 1 to November 15 under alternative F would result in long-term beneficial impacts because it would reduce the potential for disturbance to birds that could result in mortality. Beneficial impacts under alternative F would be greater than those under alternatives B or E, due to the restrictions beginning at 9:00 p.m. instead of 10:00 p.m.

*Authorized Commercial Vehicles.* Management of commercial fishing vehicles would be the same as under alternative A. Commercial fishermen would not be required to obtain an ORV permit, and commercial fishing vehicles would be authorized to enter VFAs except for resource closures and lifeguarded beaches. These management measures would result in long-term negligible adverse impacts from the presence of commercial fishing vehicles, with long-term minor to moderate benefits from night-driving restrictions.

*Permits/Carrying Capacity.* Alternative F would require a permit for ORV use, including night driving. As stated in these sections, the educational information provided by the required permit would result in benefits to state-listed/sensitive species as ORV users would be more aware of the regulations in place to protect these species, which would likely result in a higher level of compliance. There would be no impacts related to carrying capacity as ORV use would not be permitted within resource protection areas.

*Pets/Other Recreational Activity Restrictions.* Pets would be permitted throughout the Seashore in accordance with 36 CFR 2.15, which applies to all units of the national park system and prohibits pet owners from “failing to crate, cage, restrain on a leash which shall not exceed 6 feet in length, or otherwise physically confine a pet at all times.” In addition pets would be prohibited within resource closures and in areas of pedestrian shoreline access in areas in front of (i.e., seaward of) bird prenesting closures. These regulations would reduce the likelihood of pet disturbance in state-listed/special status species breeding areas; however, compliance is needed to ensure that this reduces the risk of impacts. Camping restrictions would be the same as those under alternative C. For beach fires, a non-fee educational permit would be required (the same as alternative C) and fires would be prohibited from 10:00 p.m. to 6:00 a.m. year-round. In addition, from May 1 to November 15 beach fires would be permitted only in front of Coquina Beach, Rodanthe, Waves, Salvo, Avon, Buxton, Frisco, Hatteras Village, and Ocracoke day use area. These additional restrictions during breeding season would result in long-term beneficial impacts to species at the Seashore as recreational pressures to state-listed/special status species would be further reduced.

*Overall Impact of ORV and Other Recreational Use.* The overall impact of ORV and other recreational use for each species under alternative F would be as follows:

- American oystercatcher. Implementation of a permit system with an educational component, larger buffer sizes, seasonal night-driving restrictions, prohibition of pets in the shoreline access seaward of prenesting closures, and establishment of year-round and seasonal VFAs would benefit the American oystercatcher. Establishment of prenesting closures and VFAs would provide a proactive method of limiting recreational uses early in the breeding season, and limit the potential for impacts to state-listed/special status species. However, alternative F does provide for management similar to ML2 procedures, which provide for some level of pedestrian or ORV access throughout the Seashore, which introduces the potential for impacts to the species. As there would be some protection measures in place, but recreational use could still have impacts to the species, impacts to American oystercatchers would be long-term minor to moderate adverse.

- Colonial waterbirds. Impacts to colonial waterbirds from ORV and other recreational use would be long-term minor to moderate adverse, for the same reasons as American oystercatchers under this alternative.
- Wilson's plover. Impacts to Wilson's plover from ORV and other recreational use would be long-term minor adverse. Although this species would face the same adverse impacts as American oystercatchers and colonial waterbirds, it also tends to utilize closures for piping plover, in addition to the buffers/closures provided specifically for this species, and would therefore be provided slightly more protection than other state-listed/special status species.
- Red knot. Impacts to red knot from ORV and other recreational use would be long-term minor adverse due to the nonbreeding closures and year-round VFAs provided under alternative F.

**Cumulative Impacts.** Cumulative actions and their associated impacts under alternative F would be the same as those described under alternatives A, B, C, D, and E (long-term minor to moderate adverse). Although alternative F provides additional protection that would be beneficial to state-listed / special status bird species, the adverse effects on birds from other actions occurring in the region would still exist. The cumulative impact of these past, current, and reasonably foreseeable future actions would be minor to moderate adverse. These impacts, when combined with the long-term beneficial and long-term minor to moderate adverse impacts of alternative F, would have long-term minor to moderate adverse cumulative impacts.

**Conclusion.** Overall, impacts to state-listed/special status species under alternative F would be as follows:

- American oystercatcher. Establishment of prenesting closures and larger, pre-set buffers, as well as the designation of year-round and seasonal VFAs, would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts from human disturbance during field activities, resources management activities on the whole would provide information and result in actions that would be beneficial to the species. Implementation of prenesting closures that provide a proactive resource closure early in the breeding season, a permit system with an educational component, seasonal night-driving restrictions, as well as larger buffer sizes and earlier prenesting closures, would provide long-term beneficial impacts to the American oystercatcher, greater than those under alternative B. Prohibition of pets in the shoreline access seaward of prenesting closures and establishment of nonbreeding closures would benefit the American oystercatcher. Alternative F manages the Seashore using similar buffers to the ML2 procedures (alternatives C, D, and E), which provide for pedestrian or ORV access into these areas and introduces the potential for impacts to the species. Although there would be some protection measures in place, recreational disturbance could result in long-term minor to moderate adverse impacts to American oystercatchers.
- Colonial waterbirds. Impacts to colonial waterbirds from resources management activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers. Impacts to colonial waterbirds from ORV and other recreational use would be long-term minor to moderate adverse, for the same reasons as American oystercatcher under this alternative.
- Wilson's plover. Impacts to Wilson's plover from resources management activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers, with slightly greater benefits as this species would also benefit from the management measures applied to piping plover. Impacts to Wilson's plover from ORV and other recreational use would be long-term minor adverse. Although this species would face the same adverse impacts as American oystercatchers and colonial waterbirds, it also tends to utilize closures for piping plover, in

addition to closures/buffers specifically for this species, and would therefore be provided slightly more protection than other state-listed/special status species.

- Red knot. Many of the surveying and field activities would occur outside of the primary time when red knot are present at the Seashore. Therefore, any impacts to this species from surveying and field activities would be long-term negligible adverse. However, the ability of this species to use wintering closures that have been established for piping plover as well as the establishment of year-round VFAs, would be beneficial, and overall result in long-term beneficial impacts to the species when compared to alternatives A and B. Impacts to red knot from ORV and other recreational use would be long-term minor adverse due to the additional nonbreeding closures (from VFAs and wintering piping plover closures) provided under alternative F that offer this wintering species further protection.

Cumulative impacts under alternative F would be long-term minor to moderate adverse.

**TABLE 55. SUMMARY OF IMPACTS TO STATE-LISTED AND SPECIAL STATUS SPECIES UNDER THE ALTERNATIVES**

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
American Oystercatcher – Resources Management Activities					
<p>Impacts would be long-term minor to moderate adverse as surveying and lack of specific prenesting closures for this species may miss early nesters. Piping plover prenesting closures, which could be utilized by this species as well, would not protect a number of American oystercatcher nest sites used in recent years. Also, buffer distances based on bird behavior may not provide adequate protection for the species.</p>	<p>Establishment of piping plover prenesting closures earlier in the season that could be used by oystercatchers and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts related to human disturbance during field activities, resources management activities on the whole would provide information and result in actions that would be beneficial to the species.</p>	<p>Implementation of 10 SMAs that are closed to ORVs during the breeding season would provide a proactive resource closure early in the breeding season. Establishment of prenesting closures earlier in the season and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts related to human disturbance during field activities, on the whole, resources management activities would provide information that would enable the implementation of adaptive management initiatives and contribute to better management. These activities would result in long-term beneficial impacts to the American oystercatcher, greater than those provided under alternative B.</p>	<p>Establishment of 10 SMAs that are closed to ORVs year-round and all managed under ML1 procedures during the breeding season would provide long-term benefits to breeding and wintering American oystercatchers, greater than those under alternative C. Additional benefits would be provided from surveying and closures outside of these established SMAs, as well as from the education and outreach provided. These surveying and field activities would provide information that would enable the implementation of adaptive management initiatives and contribute to better management. These activities would result in long-term beneficial impacts to this species, greater than those provided under alternative B.</p>	<p>Implementation of 10 SMAs, 7 of which are closed to ORVs during the breeding season, would provide a proactive resource closure early in the breeding season. Establishment of prenesting closures earlier in the season and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts from human disturbance during field activities, resources management activities on the whole would provide information that would enable the implementation of adaptive management initiatives and contribute to better management. These activities would result in long-term beneficial impacts to this species, greater than those provided under alternative B.</p>	<p>Implementation of prenesting closures would provide a proactive resource closure early in the breeding season. Seasonal and year-round VFAs that total 39 miles of Seashore would provide additional areas of the Seashore with less disturbance for shorebirds. Establishment of prenesting closures earlier in the season and establishment of larger, pre-set buffers would result in long-term beneficial impacts to American oystercatchers. While there would still be minor adverse impacts related to human disturbance during field activities, resources management activities on the whole would provide information that would enable the implementation of adaptive management initiatives and contribute to better management. These activities would result in long-term beneficial impacts to the species, greater than those provided under alternative B.</p>

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
American Oystercatcher – ORV And Other Recreational Use					
<p>Impacts would be long-term moderate to major adverse as buffers that adjust frequently based on bird behavior are more subject to non-compliance. The lack of designated VFAs, a permitting system, carrying capacity, or seasonal night-driving restrictions, and allowing pets at the Seashore during breeding season would contribute to these adverse impacts.</p>	<p>Establishment of prenesting closures for piping plover earlier in the season, implementation of larger, more immediate buffers, longer lasting closures for American oystercatchers once breeding behavior occurs, and night-driving restrictions would benefit the American oystercatcher. However, recreational use, with no carrying capacity, would still occur in the vicinity of this species and the established buffers may not be large enough to afford adequate protection. Because the birds would not be under constant observation, disturbance may go undetected and implementation of adequate buffers may be delayed in some nesting locations. Compliance with closures may not be absolute, resulting in minor to moderate adverse impacts if non-compliance occurs. Further adverse impacts would result from allowing pets in the Seashore during breeding season, resulting in the possibility of non-compliance with these regulations. Because of these</p>	<p>Implementation of a permit system with an educational component, larger buffer sizes, seasonal night-driving restrictions, establishment of breeding and nonbreeding SMAs, and not allowing pets in SMAs would benefit the American oystercatcher. SMAs would provide a proactive method of limiting recreational uses early in the breeding season, and limit the potential for impacts to state-listed/special status species. However, alternative C does manage three SMAs under ML2 procedures, which provide for some level of pedestrian access into these areas and introduces the potential for impacts to the species. Although there would be some protection measures in place, ORV and other recreational use could still have impacts to the species, resulting in long-term minor to moderate adverse impacts to American oystercatchers.</p>	<p>Providing large SMAs that are closed year-round to ORVs and closed to pedestrians during the breeding season would provide large undisturbed areas for both breeding and nonbreeding oystercatchers. Further benefits would be provided by seasonal night-driving restrictions, the establishment of a permit system with an educational component, and prohibition of pets in SMAs year-round. With these measures in place, impacts to American oystercatchers from ORV and other recreational use would be long-term minor adverse, as the chance of disturbance still exists, but would be lower than that under the other alternatives evaluated.</p>	<p>Implementation of a permit system with an educational component, larger buffer sizes, seasonal night-driving restrictions, restrictions on pets in SMAs, and establishment of breeding and nonbreeding SMAs would benefit the American oystercatcher. SMAs would provide a proactive method of limiting recreational uses early in the breeding season, and limit the potential for impacts to state-listed/special status species. However, alternative E does allow an ORV access corridor at three SMAs managed under ML2 procedures during the breeding season (more than the other action alternatives), which provide for some level of pedestrian or ORV access into these area, which introduces the potential for impacts to the species. Although there would be some protection measures in place, recreational use could still result in long-term minor to moderate adverse impacts to American oystercatchers.</p>	<p>Implementation of a permit system with an educational component, prenesting closures, seasonal night-driving restrictions, allowing pets under the regulations of 36 CFR 2.15 with the additional prohibition of pets in resource closures and in pedestrian shoreline access areas in front of (i.e., seaward of) bird prenesting closures and establishment of seasonal and year-round VFAs that total 39 miles of Seashore would benefit the American oystercatcher. Prenesting closures would provide a proactive method of limiting recreational uses early in the breeding season, and limit the potential for impacts to state-listed/special status species, with additional areas that are relatively less disturbed provided by prenesting closures. However, alternative F does manage all areas of the Seashore to allow for ORV and/or pedestrian access, which introduces the potential for impacts to the species. As there would be some protection</p>

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
	factors, impacts to American oystercatchers from ORV use and other recreational activities would be long-term moderate adverse.				measures in place, but recreational use could still have impacts to the species, impacts to American oystercatchers would be long-term minor to moderate adverse.
Colonial Waterbirds – Resources Management Activities					
Impacts would be long-term minor to moderate adverse as no prenesting closures would be established for colonial waterbirds. Some species, such as terns and black skimmers may be able to utilize the prenesting closures established for piping plovers; however, those prenesting areas would not protect a number of colonial waterbird nest sites used in recent years. Also, buffer distances based on bird behavior may not provide adequate protection for the species.	Establishment of piping plover prenesting closures earlier in the season that would be used by some colonial waterbird species and establishment of larger, pre-set buffers would result in long-term beneficial impacts to colonial waterbirds. While there would still be minor adverse impacts related to human disturbance during field activities, resources management activities on the whole would provide information and result in actions that would be beneficial to the species.	Impacts to colonial waterbirds from surveying and field activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers.	Impacts to colonial waterbirds from surveying and field activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers.	Impacts to colonial waterbirds from resources management activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers.	Impacts to colonial waterbirds from resources management activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers.
Colonial Waterbirds – ORV And Other Recreational Use					
Impacts would be long-term moderate to major adverse as buffers may not be adequate to protect the species, and disturbance from recreational uses is more likely. The lack of designated VFAs, a permitting system, carrying capacity, or seasonal night-driving restrictions,	Impacts to colonial waterbirds from ORV and other recreational use would be long-term moderate adverse, for the same reasons as American oystercatchers under this alternative.	Impacts to colonial waterbirds from ORV and other recreational use would be long-term minor to moderate adverse, for the same reasons as American oystercatchers under this alternative.	Impacts to colonial waterbirds from ORV and other recreational use would be long-term minor adverse, for the same reasons as American oystercatchers under this alternative.	Impacts to colonial waterbirds from ORV and other recreational use would be long-term minor to moderate adverse, for the same reasons as those discussed above for American oystercatchers under this alternative.	Impacts to colonial waterbirds from ORV and other recreational use would be long-term minor to moderate adverse, for the same reasons as American oystercatchers under this alternative.

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
and allowing pets in the vicinity of breeding birds would also contribute to adverse impacts.					
Wilson's Plover – Resources Management Activities					
Impacts would be long-term minor adverse as the habitat for this species would be well surveyed during piping plover surveys and this species would be able to take advantage of management measures for piping plover as their breeding seasons and habitat requirements are similar. Also, buffer distances based on bird behavior may not provide adequate protection for the species. Some benefits may occur from incidental management of Wilson's plover during piping plover management activities, both during breeding and nonbreeding seasons.	Establishment of piping plover prenesting closures earlier in the season that could be used by other species and establishment of larger, pre-set buffers for piping plover, used by Wilson's plover, would result in long-term beneficial impacts to Wilson's plover. While there would still be minor adverse impact related to human disturbance during field activities, species surveying and field activities on the whole would provide information and result in actions that would be beneficial to the species.	Impacts to Wilson's plover from surveying and field activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers, with slightly greater benefits as this species would also benefit from the management measures applied to piping plover.	Impacts to Wilson's plover from surveying and field activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers, with slightly greater benefits as this species would also benefit from the management measures applied to piping plover.	Impacts to Wilson's plover from resources management activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers, with slightly greater benefits as this species would also benefit from the management measures applied to piping plover.	Impacts to Wilson's plover from resources management activities would be long-term beneficial, for the same reasons as discussed above for American oystercatchers, with slightly greater benefits as this species would also benefit from the management measures applied to piping plover.
Wilson's Plover – ORV And Other Recreational Use					
Impacts would be long-term moderate to major adverse as no specific management would be provided for this species, although they could utilize buffers and closures established for piping plover. The lack of designated	Impacts to Wilson's plover from ORV and other recreational use would be long-term minor to moderate adverse. Although this species would face the same adverse impacts as American oystercatchers and colonial waterbirds, it also tends to	Impacts to Wilson's plover from ORV and other recreational use would be long-term minor adverse, less than those under alternative A and B. Although this species would face the same adverse impacts as American oystercatchers and	Impacts to Wilson's plover from ORV and other recreational use would be long-term negligible to minor adverse. Although this species would face the same adverse impacts as American oystercatchers and colonial waterbirds, it also tends to	Impacts to Wilson's plover from ORV and other recreational use would be long-term minor adverse. Although this species would face the same adverse impacts as American oystercatchers and colonial waterbirds, it also tends to	Impacts to Wilson's plover from ORV and other recreational use would be long-term minor adverse. VFAs, a permitting system, carrying capacity, or seasonal night-driving restrictions, and allowing pets at the Seashore during breeding season would contribute to these adverse impacts.	utilize closures for piping plover and would therefore be provided slightly more protection than other state-listed/special status species.	colonial waterbirds, it also tends to utilize the closures for piping plover, in addition to the specific buffers/closures provided for the species, and would therefore be provided slightly more protection than other state-listed/special status species.	utilize closures for piping plover, in addition to the buffers/closures provided specifically for this species, and would therefore be provided slightly more protection than other state-listed/special status species.	utilize closures for piping plover, in addition to the buffers/closures provided specifically for this species, and would therefore be provided slightly more protection than other state-listed/special status species.	utilize closures for piping plover, in addition to the buffers/closures provided specifically for this species, and would therefore be provided slightly more protection than other state-listed/special status species.
<b>Red Knot – Resources Management Activities</b>					
Many of the surveying and field activities for other species would occur outside of the primary time when the red knot is a resident at the Seashore. Therefore, any impacts to this species from surveying and field activities for other species would be long-term negligible adverse.					
Impacts to nonbreeding red knot would be long-term minor adverse as their prime foraging habitat (ocean shoreline) would not be afforded protection by nonbreeding closures, although the ability of this species to use wintering closures for piping plover at inlets and Cape Point would result in some benefit.	The red knot would benefit from extended breeding season closures for other species and from wintering closures for piping plover at the inlets and Cape Point. Impacts to nonbreeding red knot would be long-term minor adverse as their prime foraging habitat (ocean shoreline) would not be afforded protection by nonbreeding closures.	Nonbreeding shorebird SMAs and the establishment of VFAs along the ocean shoreline would result in beneficial impacts to nonbreeding red knots. However, the ability of this species to use wintering closures that have been established for piping plover as well as the establishment of SMAs, some of which are closed to ORVs year-round, would be beneficial to those red knot that happen to use those areas, and overall result in long-term beneficial impacts to the species when compared to alternatives A and B.	Nonbreeding shorebird SMAs and the establishment of VFAs along the ocean shoreline would result in beneficial impacts to nonbreeding red knots. However, the ability of this species to use wintering closures that have been established for piping plover as well as the establishment of SMAs, all of which are closed to ORVs year-round would result in long-term beneficial impacts to red knot when compared to all other alternatives.	The ability of this species to use wintering closures that have been established for piping plover as well as the establishment of SMAs, some of which are closed year-round, would be beneficial, and overall result in long-term beneficial impacts to the species when compared to alternatives A and B.	The ability of this species to use wintering closures that have been established for piping plover as well as the establishment of year-round and seasonal VFAs over 39 miles of the Seashore (of which 26 miles would be year-round and provide protection of non-breeding habitat, would be beneficial, and overall result in long-term beneficial impacts to the species when compared to alternatives A and B.
<b>Red Knot – ORV And Other Recreational Use</b>					
Impacts would be long-term moderate adverse as no specific management	Impacts to red knots from ORV and other recreational use would be long-term	Impacts to red knot from ORV and other recreational use would be long-term minor adverse	Impacts to red knot from recreation and other activities would be long-term negligible to minor	Impacts to red knot from ORV and other recreational use would be long-term minor adverse	Impacts to red knot from ORV and other recreational use would be long-term minor adverse

Alternative A	Alternative B	Alternative C	Alternative D	Alternative E	Alternative F
would be provided for this species especially during a key life stage of wintering. The lack of designated VFAs, a permitting system, or night-driving restrictions when red knots are at the Seashore, and allowing pets at the Seashore during the migrating/nonbreeding season would contribute to these adverse impacts. Impacts to red knots would be lower than other species as they would not be subject to impacts during their breeding cycle and their use of the Seashore corresponds to times of lower visitation.	moderate adverse as no specific management would be provided for this species especially during a key life stage of wintering. Although this species may benefit from longer lasting breeding season closures for other species and from winter closures established for piping plovers, the lack of designated VFAs, a year-round permitting system, no night-driving restrictions when red knots are at the Seashore, and allowing pets at the Seashore during the migrating / nonbreeding season would contribute to these adverse impacts.	due to the additional nonbreeding closures provided under alternative C that offer this wintering species further protection.	adverse due to the additional nonbreeding closures provided under alternative D that offer this wintering species further protection as well as the large year-round SMAs that would offer further protection during red knot wintering.	due to the additional nonbreeding closures provided under alternative E that offer this wintering species further protection; however, there would be greater adverse impacts than under alternatives D or F due to fewer miles of shoreline being closed to ORVs under alternative E during the nonbreeding season.	due to the wintering closures established for piping plover, as well as the 26 miles of year-round VFAs that provide less disturbed non-breeding habitat.

## WILDLIFE AND WILDLIFE HABITAT

### GUIDING REGULATIONS AND POLICIES

The Seashore’s Resource Management Plan (NPS 1997) identifies the following natural resource-related goals to provide direction for future management of the Seashore:

- Identify visitor uses and impacts to establish appropriate management policies that would meet the needs of the Seashore visitor while providing for the preservation and protection of the resources unimpaired for future generations.
- Continue to provide rigorous enforcement, research, environmental surveying, and applied resource management in accordance with available funding and direction.
- Continue to closely monitor and regulate recreational use in accordance with environmental, ecological, and preservation considerations.

Service-wide NPS regulations and policies, including the NPS *Organic Act of 1916*, NPS *Management Policies 2006* (NPS 2006c), and the NPS Natural Resource Management Reference Manual 77, also direct national parks to provide for the protection of Seashore resources. The *Organic Act* directs national parks to conserve wildlife unimpaired for future generations and is interpreted to mean that native animal life is to be protected and perpetuated as part of a park unit’s natural ecosystem. Parks rely on natural

processes to control populations of native species to the greatest extent possible; otherwise, they are protected from harvest, harassment, or harm by human activities.

The NPS *Management Policies 2006* state that the NPS “will maintain as parts of the natural ecosystems of parks all plants and animals native to park ecosystems. The term “plants and animals” refers to all five of the commonly recognized kingdoms of living things and includes such groups as flowering plants, ferns, mosses, lichens, algae, fungi, bacteria, mammals, birds, reptiles, amphibians, fishes, insects, worms, crustaceans, and microscopic plants or animals.” The NPS will achieve this by:

- preserving and restoring the natural abundances, diversities, dynamics, distributions, habitats, and behaviors of native plant and animal populations and the communities and ecosystems in which they occur;
- restoring native plant and animal populations in parks when they have been extirpated by past human-caused actions; and
- minimizing human impacts on native plants, animals, populations, communities, and ecosystems, and the processes that sustain them (NPS 2006c).

Section 4.1 of NPS *Management Policies 2006* states that “natural resources will be managed to preserve fundamental physical and biological processes, as well as individual species, features, and plant and animal communities. The Service will not attempt to solely preserve individual species (except threatened or endangered species) or individual natural processes; rather, it will try to maintain all the components and processes of naturally evolving park ecosystems, including the natural abundance, diversity, and genetic and ecological integrity of the plant and animal species native to those ecosystems” (NPS 2006c). According to Section 8.2.2.1 of the NPS *Management Policies 2006*, “Superintendents will develop and implement visitor use management plans and take action, as appropriate, to ensure that recreational uses and activities in the park are consistent with its authorizing legislation or proclamation and do not cause unacceptable impacts on park resources or values” (NPS 2006c).

Seashore wildlife has evolved in a barrier island ecosystem, which is dependent on the continuation of natural shoreline processes. Barrier islands are highly dynamic with changes in sea level, wave and wind action, and ocean currents continuously creating and altering habitat for wildlife through the processes of erosion and accretion of shorelines and sand dunes; overwash across the islands; and the formation, migration, and closure of inlets. To protect coastal barrier processes, the NPS *Management Policies 2006* direct that natural shoreline processes such as erosion, deposition, dune formation, overwash, inlet formation, and shoreline migration will be allowed to continue without interference (NPS 2006c, sec. 4.8.1.1). The policies further state, “[w]here human activities or structures have altered the nature or rate of natural shoreline processes, the Service will, in consultation with appropriate state and federal agencies, investigate alternatives for mitigating the effects of such activities or structures and for restoring natural conditions.”

## **ASSUMPTIONS, METHODOLOGY, AND IMPACT THRESHOLDS**

The following describes the methodology used to evaluate the impacts of the proposed alternatives on general wildlife at the Seashore. This discussion focuses on those species that may potentially be impacted by the actions described in the proposed alternatives and is, therefore, directed toward specific wildlife, including invertebrates and “other” bird species (those not state or federally protected or species of special concern). The analysis is organized according to those two wildlife types. Although a number of studies have investigated ORV impacts on invertebrates found on sandy beaches, the studies have focused on a relatively small number of species, and only a few of the studies have occurred on southeastern U.S. beaches that would have similar species to the beaches of Cape Hatteras National

Seashore. There have also not been any comprehensive studies within the Seashore to determine the species composition and abundance of invertebrates within the bird foraging habitat. As a result, sufficient information is not available to provide a site-specific assessment of impacts of ORVs on all of the invertebrate species inhabiting the wrack, intertidal sand flats, island spits, and the high energy intertidal zone at the Seashore. Therefore, impacts to invertebrates are discussed in general terms, based on existing studies and, where possible, impacts on species specific to the Seashore are discussed.

Potential impacts on other bird species and their associated habitat focused on shorebirds that would likely be using the same habitats as the protected species addressed in this plan/EIS. Information about habitat and other existing data were acquired from staff at the Seashore, the USFWS, and available literature (see the Literature Review in appendix A). A comprehensive list of other bird species can be found in “Chapter 3: Affected Environment.”

For each alternative, potential impacts on wildlife and wildlife habitat were evaluated based on the pattern of proposed ORV use at the Seashore, resulting from what areas are open to ORV and other recreational uses and for what duration, the nature of habitats and species present, and the nature of coastal barrier processes that create and alter habitat. Primary steps in assessing impacts on wildlife and wildlife habitat were to determine (1) the potential for species to occur in habitats likely to be affected by management actions described in the alternatives; (2) current and future use and distribution of ORVs by alternative; (3) habitat impact or alteration caused by the alternatives; and (4) disturbance potential of the action and the potential to directly or indirectly affect wildlife or wildlife habitat as a result of ORV activities. The information contained in this analysis was obtained through best professional judgment of the Seashore staff and experts in the field and by reviewing applicable scientific literature.

A summary of impacts to wildlife and wildlife habitat under all alternatives is provided in table 56 at the end of this section. The following thresholds for evaluating impacts to wildlife and wildlife habitat were defined.

*Negligible:* There would be no observable or measurable impacts to native species, their habitats, or the natural processes sustaining them. Impacts would be well within natural fluctuations.

*Minor Adverse:* Impacts on native species, their habitats, or the natural processes sustaining them would be detectable, but would not be outside the natural range of variability. Occasional responses by some individuals to disturbance could be expected, but without interference to feeding, reproduction, resting, or other factors affecting population levels. Small changes to local population numbers, population structure, and other demographic factors might occur. However, some impacts might occur during critical reproduction periods for a species, but would not result in injury or mortality. Sufficient habitat in the Seashore would remain functional to maintain a sustainable population in the Seashore.

*Moderate Adverse:* Impacts on native species, their habitats, or the natural processes sustaining them would be detectable and could be outside the natural range of variability. Frequent responses by some individuals to disturbance could be expected, with some negative impacts to feeding, reproduction, resting, or other factors affecting local population levels. Some impacts might occur during critical periods of reproduction or in key habitats in the Seashore and result in harassment, injury, or mortality to one or more individuals. However, sufficient population numbers and habitat in the Seashore would remain functional to maintain a sustainable population in the Seashore.

*Major Adverse:* Impacts on native species, their habitats, or the natural processes sustaining them would be detectable, would be expected to be outside the natural range of variability, and would be permanent. Frequent responses by some individuals to disturbance would be expected, with negative impacts to feeding, reproduction, or other factors resulting in a decrease in Seashore population levels or a failure to restore levels that are needed to maintain a sustainable population in the Seashore. Impacts would occur during critical periods of reproduction or in key habitats in the Seashore and result in direct mortality or loss of habitat. Local population numbers, population structure, and other demographic factors might experience large declines.

*Duration:* Short-term effects would be one to two breeding seasons for bird species and one to two years for all other native species.

Long-term would be anything beyond two breeding seasons for bird species or two years for all other native species.

## Study Area

The study area for assessment of the various alternatives is the Seashore boundary. The study area for the cumulative impacts analysis is the Seashore plus the adjacent lands outside of the Seashore boundaries on Bodie, Hatteras, and Ocracoke islands.

## Impacts Common to All Alternatives

**Impacts to Invertebrates—Resources Management Activities.** Under all alternatives, species surveying and management would occur for piping plover, sea turtles, and seabeach amaranth. These surveying activities may vary in duration between alternatives, but the use of ATVs/UTVs and, in some cases, ORVs to conduct certain surveying and management activities is a constant among alternatives.

Management activities that would have the greatest potential to impact invertebrates include the use of vehicles for surveying and management because of the potential for mortality of individual invertebrates caused by compaction under vehicle tires. Seashore staff would continue to use ATVs/UTVs and occasionally ORVs to conduct bird and turtle surveys and also to establish resource closures as required based on species behavior under all alternatives. Staff would avoid driving across the wrack, an area known to contain high number of invertebrates, and would only drive during nighttime hours when patrolling for law enforcement reasons, which would limit impacts to invertebrates in this area. Driving in the wrack would be limited because studies have shown that areas closed to ORV use have higher densities of invertebrates in these areas (Landry 2004; Kluft and Ginsberg 2009; Moss and McPhee 2006). Due to the limited amount of vehicle use by staff and the fact that such use would occur predominantly during the day, impacts to beach invertebrates from resources management activities would be long-term negligible adverse across all alternatives.

**Impacts to Other Bird Species—Resources Management Activities.** Under all alternatives, Seashore staff would perform surveys of recent breeding areas for protected species and would also continue to monitor breeding, nesting, and fledging activities throughout the breeding season. Although the time and duration of these surveys may vary between alternatives, common to all alternatives is that surveying and monitoring activities would bring staff and/or vehicles into contact with other bird species, increasing the potential for disturbance. However, the majority of these other bird species are not at the Seashore during their breeding cycle, which would reduce the impacts of disturbance from resources management staff

under all alternatives. Also, many of the surveying and field activities for protected species would occur outside of the primary time when other bird species are residents at the Seashore. Because resource protection staff would also take proper measures to minimize any disturbance to these species, surveying activities associated with all alternatives would only result in negligible adverse effects on other bird species.

Also common to all alternatives is the provision of prenesting habitat closures for protected species, species closures for breeding activities, and closure of nonbreeding wintering habitat. All alternatives include the establishment of prenesting closures for recent piping plover breeding areas, and nesting buffers and closures around established territories and nests of colonial waterbirds and American oystercatchers. The symbolic fencing would deter the entry of people, pets, and ORVs into these habitats. Although the size and location of these closures vary between the alternatives, these closures would be implemented under each alternative and would benefit birds other than the piping plover, American oystercatcher, and other protected species. Species that are not listed as state or federally protected or are not species of special concern would also benefit from the management measures for protected species under all of the alternatives. However, the majority of the other bird species would not be present at the Seashore to take advantage of prenesting closures established for piping plover or other breeding bird species. Therefore, the establishment of prenesting closures would only result in minimal benefits for other bird species.

Because these other bird species are at the Seashore during wintering and migration, they would be most affected by the wintering/nonbreeding management actions included in this plan/EIS. These impacts are discussed below under each specific alternative.

**Predation.** An indirect impact from ORV and recreational use is the attraction of mammalian and bird predators to the waste stream associated with recreational use (USFWS 1996a). Although the Seashore would enforce proper trash disposal and anti-wildlife feeding regulations, recreational use would continue to have indirect impacts on other bird species through the attraction of predators. These predators are a well-known factor in nest failure for piping plovers and all ground nesting birds within the Seashore. However, because the majority of these other bird species do not breed at the Seashore, they are not subject to predation pressures during this life cycle stage. However, under all alternatives, some adult migratory bird species could still be taken by predators, resulting in long-term negligible to minor adverse impacts to other bird species at the Seashore.

### **Impacts of Alternative A: No Action—Continuation of Management under the Interim Protected Species Management Strategy**

Under alternative A, there would be no construction activities implemented and therefore no construction related impacts would occur to wildlife or wildlife habitat. Activities that could potentially impact wildlife and wildlife habitat under alternative A would be associated with species surveying and management, the continued recreational use of ORVs, and pedestrian activity.

#### **Impacts to Other Bird Species**

**Resources Management Activities.** No nonbreeding closures would be established for other bird species, although these species could utilize the nonbreeding closures for piping plover that would include suitable interior habitats at spits and at Cape Point year-round. Being able to utilize other species closures would have some long-term benefits, as some protection is offered during this sensitive life stage. However, these closures would not be specific to other bird species and would not include ocean beach habitat, resulting in long-term minor adverse impacts to other bird species.

**ORV and Other Recreational Use.** Under this alternative, visitors would be allowed to operate ORVs on all the ocean and inlet shoreline and on the existing soundside routes, 24 hours per day year-round, subject to temporary resource closures, seasonal ORV closures in front of the villages, and temporary ORV safety closures (see figure 2, chapter 2, alternative A and B maps). ORV and other recreational activities that occur in the months when other bird species are in residence on Seashore beaches have the potential to impact resting and foraging birds from vehicle use and associated noise and presence of people and pets. Of particular concern is when these disturbance factors result in birds being forced to fly while they are foraging, known as frequent escape flight. Frequent escape flights result in a reduction in time foraging and an increase in the time spent flying. Because foraging is replaced with flying, birds would not be able to add the body fat they need for migration, resulting in long-term minor to moderate adverse impacts.

Because this alternative would allow an unlimited number of vehicles and pedestrians to access most areas of the Seashore 24 hours a day, there is the potential for frequent disturbance to other bird species. Even though buffers would be established for protected species (which could be used by other bird species), it is likely that some birds could be disturbed by recreational or commercial fishing activities as vehicles disturbance can affect nonbreeding birds (Tarr 2008).

As noted in chapter 3, a 3-year study on Cape Cod and Fire Island, New York (Kluft and Ginsberg 2009), found that higher ORV traffic resulted in dispersal and desiccation of the wrack line, thereby reducing the population of invertebrates in that area. Alternative A would allow for beach driving during the day outside of resource closures, with no restrictions on night driving. This level of access would result in long-term minor to moderate impacts expected to invertebrate populations (as described below), and therefore would reduce the food source to other bird species at the Seashore, resulting in long-term moderate impacts.

Impacts to other bird species from ORV and other recreational use would be long-term moderate adverse as no specific management would be provided for these species especially during wintering and migration, when most of these species are present at the Seashore. The lack of designated VFAs, a permitting system, or night-driving restrictions, and allowing pets at the Seashore during the migrating/nonbreeding season would contribute to these long-term moderate adverse impacts.

### **Impacts to Invertebrates**

**ORV and Other Recreational Use.** Under alternative A, ORV routes would include the all ocean and inlet shoreline and on the existing soundside routes (as described above under Other Bird Species) and would include the wrack, intertidal zone, or sand flats that would be open to ORV use unless closed by protected species closures. While the typical ORV use pattern within the Seashore is to drive on the upper beach, above the high tide line (Hardgrove pers. comm. 2005), when recreational vehicles reach their destination they may drive into the intertidal zone and Seashore. Access to commercial fishing grounds also involves operating vehicles in the intertidal zone to reach desired fishing destinations. Driving on the sands of the intertidal zone would likely have adverse impacts on invertebrates due to mortality of individual species caused by compaction under vehicle tires. Access to the intertidal zone often requires vehicles to cross over the wrack, which is normally deposited within the ORV corridor and is usually an area of high concentrations of invertebrates. Driving over the wrack would cause damage and dispersal to an important source of food and habitat for many beach invertebrates (Kluft and Ginsberg 2009; Stephenson 1999).

Impacts of night driving on ghost crab populations at the Seashore are also a concern under alternative A. Though the extent of the ghost crab populations within the Seashore has not been documented, Wolcott and Wolcott (1984) concluded that even 20–50 vehicles driving at night could impact ghost crab

populations, as demonstrated in their study at Cape Lookout National Seashore. As unlimited night driving would be allowed under alternative A, it can be expected that this level of traffic would have long-term minor to moderate adverse impacts on the ghost crab population.

In summary, the implementation of alternative A would result in long-term minor to moderate adverse impacts to invertebrate species primarily due to mortality arising from unlimited night driving in the intertidal and wrack areas.
